# UNIX TOOLBOX

This document is a collection of Unix/Linux/BSD commands and tasks which are useful for IT work or for advanced users. This is a practical guide with concise explanations, however the reader is supposed to know what s/he is doing.

Unix Toolbox revision 14.4

The latest version of this document can be found at http://cb.vu/unixtoolbox.xhtml. Replace .xhtml on the link with .pdf for the PDF version and with .book.pdf for the booklet version. On a duplex printer the booklet will create a small book ready to bind. See also the about page.

Error reports and comments are most welcome - c@cb.vu Colin Barschel.

### LSYSTEM

Hardware (p2) | Statistics (p2) | Users (p3) | Limits (p3) | Runlevels (p4) | root password (p5) | Compile kernel (p6) | Repair grub (p7) | Misc (p7)

## Running kernel and system information

```
# uname -a # Get the kernel version (and BSD version)
# lsb_release -a # Full release info of any LSB distribution
# cat /etc/SuSE-release # Get SuSE version
# cat /etc/debian_version # Get Debian version
```

Use /etc/distr-release with distr= lsb (Ubuntu), redhat, gentoo, mandrake, sun (Solaris), and so on. See also /etc/issue.

```
# uptime # Show how long the system has been running + load
# hostname # system's host name
# hostname -i # Display the IP address of the host. (Linux only)
# man hier # Description of the file system hierarchy
# last reboot # Show system reboot history
```

## 1.1 Hardware Informations

## Kernel detected hardware

```
# dmesg # Detected hardware and boot messages
# lsdev # information about installed hardware
# dd if=/dev/mem bs=lk skip=768 count=256 2>/dev/null | strings -n 8 # Read BIOS
```

#### Linux

#	#	#	#	#	#	#	#	#	#
# dmidecode	# 1shal	lsusb -tv	# lspci -tv	cat /proc/devices	free -m	# watch -n1 'cat /proc/interrupts'	# grep MemTotal /proc/meminfo	# cat /proc/meminfo	# cat /proc/cpuinfo
# Show DMI/SMBIOS: hw info from the BIOS	# Show a list of all devices with their properties	# Show USB devices	# Show PCI devices	# Configured devices	# Used and free memory (-m for MB)	# Watch changeable interrupts continuously	# Display the physical memory	# Hardware memory	# CPU model

#### FreeBSD

Show SCSI devices	# camcontrol devlist -v
Show ATA devices	# atacontrol list
Show USB devices	# usbdevs -v
Show PCI devices	# pciconf -1 -cv
# Configured devices	# sysctl dev
Kernel memory settings and info	# sysctl -a   grep mem
Hardware memory	# sysctl hw.realmem
# Memory usage	# sysctl vm
# number of active CPUs installed	# sysctl hw.ncpu
# Gives a lot of hardware information	# sysctl hw
# CPU model	# sysctl hw.model

# 1.2 Load, statistics and messages

The following commands are useful to find out what is going on on the system.

```
# top # display and update the top cpu processes # mpstat 1 # display virtual memory statistics # vmstat 2 # display virtual memory statistics # iostat 2 # display I/O statistics (2 s intervals) # systat -vmstat 1 # BSD summary of system statistics (1 s intervals) # systat -tcp 1 # BSD tcp connections (try also -ip) # systat -netstat 1 # BSD active network connections # systat -ifstat 1 # BSD network traffic through active interfaces
```

### Online Help

Short Linux reference www.pixelbeat.org/cmdline.html Little command line goodieswww.shell-fu.org

That's all folks!

System

# systat -iostat 1 # BSD CPU and and disk throughput
# ipcs -a # information on System V interprocess
# tail -n 500 /var/log/messages # Last 500 kernel/syslog messages
# tail /var/log/warn # System warnings messages see syslog.conf

### 1.3 Users

# Add group "admin" and user colin (Linux/Solaris) # Show the active user id with login and group FreeBSD delete user joe (interactive) # Add existing user to group (Debian) FreeBSD add user joe (interactive) Add existing user to group (SuSE) Delete user colin (Linux/Solaris) Show last logins on the system Show who is logged on the system # Use pw on FreeBSD # Add a new member to a group pw groupadd admin
# Use pw on FreeBSD
pw groupmod admin -m newmember # Add a new member to a gro
pw useradd colin -c "Colin Barschel" -g admin -m -s /bin/tcsh useradd -c "Colin Barschel" -g admin -m colin pw userdel colin; pw groupdel admin usermod -a -G <group> <user> groupmod -A <user> <group> groupadd admin userdel colin adduser joe rmuser joe id last

Encrypted passwords are stored in /etc/shadow for Linux and Solaris and /etc/master.passwd on FreeBSD. If the master.passwd is modified manually (say to delete a password), run #  $pwd_mkdb$ -p master.passwd to rebuild the database.

To temporarily prevent logins system wide (for all users but root) use nologin. The message in nologin will be displayed (might not work with ssh pre-shared keys).

# echo "Sorry no login now" > /etc/nologin # (Linux) # echo "Sorry no login now" > /var/run/nologin # (FreeBSD)

### 1.4 Limits

Some application require higher limits on open files and sockets (like a proxy web server, database). The default limits are usually too low.

#### Linux

### Per shell/script

The shell limits are governed by ulimit. The status is checked with ulimit —a. For example to change the open files limit from 1024 to 10240 do:

# ulimit -n 10240 # This is only valid within the shell

The ulimit command can be used in a script to change the limits for the script only.

### Per user/process

Login users and applications can be configured in  $/\mathtt{etc/security/limits.conf.}$  For example:

### System wide

Kernel limits are set with sysctl. Permanent limits are set in /etc/sysctl.conf.

```
# sysctl -a
# view all system limits
# sysctl fs.file-max
# view max open files limit
# sysctl fs.file-max=102400
# change max open files limit
# coto "1024 500000" > /proc/sys/net/ipv4/ip_local_port_range # port range
# cat /etc/sysctl.conf
# Permanent entry in sysctl.conf
# cat /proc/sys/fs/file-nr
# cat /proc/sys/fs/file-nr
```

#### FreeBSD

### Per shell/script

Use the command  $\mathtt{limits}$  in csh or tcsh or as in Linux, use  $\mathtt{ulimit}$  in an sh or bash shell

### Per user/process

system maximal value. The default limits on login are set in /etc/login.conf. An unlimited value is still limited by the

### System wide

Kernel limits are also set with sysctl. Permanent limits are set in /etc/sysctl.conf or /boot/ loader.conf. The syntax is the same as Linux but the keys are different.

```
# sysctl -a
                                                                                                                                 kern.ipc.somaxconn=8192
                                                                                                                                                         kern.maxfilesperproc=32768
                                                                                                                                                                                                 kern.maxfiles=65536
                                                                                                                                                                                                                                kern.ipc.nmbclusters=32768
                                                                                                                                                                                                                                                                  # sysctl kern.maxfiles=XXXX
                           sysctl net.inet.ip.portrange.last=50000 # Default is 1024-5000
                                                             sysctl kern.ipc.numopensockets
                                                                                               sysctl
                                                                                               kern.openfiles
# network memory buffers statistics
                                                                How many open sockets are in use
                                                                                            How many file descriptors are in use
                                                                                                                                                                                              Typical values for Squid
                                                                                                                                                                                                                                Permanent entry in /etc/sysctl.conf
                                                                                                                                                                                                                                                                  maximum number of file descriptors
                                                                                                                                                                                                                                                                                                 View all system limits
                                                                                                                                 TCP queue. Better for apache/sendmail
```

See The FreeBSD handbook Chapter  $11^{
m i}$  for details. And also FreeBSD performance tuning $^2$ 

#### Solaris

The following values in  $/ ext{etc/system}$  will increase the maximum file descriptors per proc:

```
set rlim_fd_cur = 1024
                                          set rlim_fd_max = 4096
# Hard limit on file descriptors for a single proc
# Soft limit on file descriptors for a single proc
```

#### 1.5 Runlevels

runlevel. The scripts are stored in /etc/init.d and are linked into /etc/rc.d/rcN.d with N the runlevel Once booted, the kernel starts init which then starts rc which starts all scripts belonging to a

The default runlevel is configured in /etc/inittab. It is usually 3 or 5:

```
# grep default: /etc/inittab
```

The actual runlevel can be changed with init. For example to go from 3 to 5:

0 # init 2	Shutdown and halt # Enters runLevel 5
_	Single-User mode (also S)
2	Multi-user without network
ω	Multi-user with network
5	Multi-user with X
6	Reboot

Use chkconfig to configure the programs that will be started at boot in a runlevel

```
chkconfig sshd off
                           chkconfig sshd --level 35 on
                                                     chkconfig --list sshd
Disable sshd for all runlevels
                         Configure sshd for levels 3 and 5
                                                     Report the status of sshd
                                                                              List all init scripts
```

manage the runlevels scripts. Default is to start in 2,3,4 and 5 and shutdown in 0,1 and 6. Debian and Debian based distributions like Ubuntu or Knoppix use the command update-rc.d to

## The program simplecpp.cpp

```
int main (int argc, char* argv[]) {
                                                                                                                                                                    using namespace std;
                                                                                                                                                                                                                                  #include <iostream>
                                                                                                                                                                                                    #include <string>
unsigned long ipint = 1347861486;
GenericUtils:::IPv4 iputils;
ipstr = iputils.IPint_to_IPquad(ipint);
cout << ipint << " = " << ipstr << endl;</pre>
                                                                                                              string ipstr;
// define variables
// The IP in integer form
// create an object of the class
// call the class member
// print the result
```

## Compile and execute with:

```
1347861486 = 80.86.187.238
                                                                                  # g++ -c IPv4.cpp simplecpp.cpp
                                                         g++ IPv4.o simplecpp.o -o simplecpp.exe
                              ./simplecpp.exe
                                                      # Link the objects to final executable
                                                                                       # Compile in objects
```

to check if a shared library is missing or if the executable is static. Use  $\operatorname{\mathtt{1dd}}$  to check which libraries are used by the executable and where they are located. Also used

```
# nm version.o
                                                                                                                           # ldd /sbin/ifconfig
                             ar x /usr/lib/libc.a version.o
                                                             ar t staticlib.a
                                                                                           ar rcs staticlib.a *.o
# show function members provided by object
                             extract an object file from the archive
                                                                                           create static archive
                                                          print the objects list from the archive
                                                                                                                        list dynamic object dependencies
```

## 22.5 Simple Makefile

The minimal Makefile for the multi-source program is shown below. The lines with instructions *must begin with a tab*! The back slash "\" can be used to cut long lines.

```
clean:
                                          simplecpp: ${OBJS}
${CC} -o simplecpp ${CFLAGS} ${OBJS}
                                                                                                            OBJS = IPv4.o simplecpp.o
                                                                                                                                                          cc = g++
rm -f ${TARGET} ${OBJS
```

### Programming

```
gcc simple.c -o simple
                                      The answer is 42
```

## 22.3 C++ basics

```
Address of object obj.

Member x of class obj (object obj)

Member x of class pointed to by pobj
(*pobj).x and pobj->x are the same
*pointer
                                                            x<-[qod
                                          x. [qo
                      &obj
```

## 22.4 C++ example

As a slightly more realistic program in C++: a class in its own header (IPv4.h) and implementation (IPv4.cpp) and a program which uses the class functionality. The class converts an IP address in integer format to the known quad format.

**IPv4 class** 

#### IPV4.h:

```
// create a namespace
// class definition
                                                                                                                                                                                              std::string IPint_to_IPquad(unsigned long ip); // member interface
                                                                                                                                                                                                                                           //namespace GenericUtils
                                                                                               namespace GenericUtils {
                                                                                                                                                                   IPv4(); ~IPv4();
                                                    #include <string>
                                                                                                                                                                                                                                                                    #endif // IPV4 H
#ifndef IPV4 H
                           #define IPV4 H
                                                                                                                     class IPv4 {
```

#### IPv4.cpp:

```
// default constructor/destructor
                                                                                                                                                                   string IPv4::IPint_to_IPquad(unsigned long ip) { // member implementation
                                                                                                                                                                                                            // Bitwise right shift
                                                                                                                                                                                        // use a stringstream
                                                               use the namespaces
                                                                                                                                                                                                                              ipstr << ((ip &Oxff000000) >> 24)
                                                                                   using namespace GenericUtils;
                                                                                                                                                                                          ostringstream ipstr;
                                                                 using namespace std;
                                         #include <sstream>
#include "IPv4.h"
                     #include <string>
                                                                                                                                                 IPv4::~IPv4() {}
                                                                                                                           IPv4::IPv4() {}
```

### System

```
update-rc.d sshd start 20 2 3 4 5 . stop 20 0 1 6 . # With explicit arguments update-rc.d -f sshd remove # Disable sshd for all runlevels
# Activate sshd with the default runlevels
                                                                                                                                                shutdown -h now (or # poweroff) # Shutdown and halt the system
update-rc.d sshd defaults
```

#### FreeBSD

The BSD boot approach is different from the SysV, there are no runlevels. The final boot state rc.d/ and in /usr/local/etc/rc.d/ for third-party applications. The activation of the service is single user, with or without X) is configured in /etc/ttys. All OS scripts are located in /etc/ configured in /etc/rc.conf and /etc/rc.conf.local. The default behavior is configured in /etc/ defaults/rc.conf. The scripts responds at least to start|stop|status.

```
# Go into single-user mode
# Go back to multi-user mode
# Shutdown and halt the system
                    sshd is running as pid 552. # shutdown now
# /etc/rc.d/sshd status
                                                                                       shutdown -p now
shutdown -r now
```

The process init can also be used to reach one of the following states level. For example # init 6 for reboot.

```
Halt and turn the power off (signal USR2)
```

- Go to single-user mode (signal TERM) Reboot the machine (signal INT) 9
  - Block further logins (signal ISTP) U
    - Rescan the ttys(5) file (signal HUP)

#### Windows

Start and stop a service with either the service name or "service description" (shown in the Services Control Panel) as follows:

```
# same as above using descr.
                         # start search service
                                                                             net start "Windows Search"
                                                   net stop "Windows Search"
net stop WSearch
```

## 1.6 Reset root password

### Linux method 1

At the boot loader (lilo or grub), enter the following boot option:

init=/bin/sh

The kernel will mount the root partition and init will start the bourne shell instead of xc and then a runlevel. Use the command passwd at the prompt to change the password and then reboot. Forget the single user mode as you need the password for that.

If, after booting, the root partition is mounted read only, remount it rw:

```
# or delete the root password (/etc/shadow)
                                                              # sync before to remount read only
                                                                 sync; mount -o remount, ro /
mount -o remount, rw /
```

## FreeBSD method 1

On FreeBSD, boot in single user mode, remount / rw and use passwd. You can select the single user mode on the boot menu (option 4) which is displayed for 10 seconds at startup. The single user mode will give you a root shell on the / partition.

```
# will mount / rw
# mount -u /; mount -a
                passwd
```

26

### System —

# Unixes and FreeBSD and Linux method 2

partition from an other OS (like a rescue CD) and change the password on the disk. Other Unixes might not let you go away with the simple init trick. The solution is to mount the root

- Boot a live CD or installation CD into a rescue mode which will give you a shell.
  Find the root partition with fdisk e.g. fdisk /dev/sda
- Mount it and use chroot:

```
chroot /mnt
                    mount -o rw /dev/ad4s3a /mnt
chroot into /mnt
```

## 1.7 Kernel modules

#### Linux

```
FreeBSD
  # kldload crypto
                                                                                                                  # modprobe isdn
                                                                                                                                           Lsmod
                                                                                                                     # List all modules loaded in the kernel
# To load a module (here isdn)
To load a module (here crypto)
                           List all modules loaded in the kernel
```

## 1.8 Compile Kernel

#### Linux

```
make
make install
                make modules_install
                                                              make
                                                                                make menuconfig
                                                                                                    make oldconfig
                                                                                                                          make mrproper
                                                                                                                                                cd /usr/src/linux
                                          modules
                                          Compile the modules
                                                          Create a compressed kernel image
                                                                              or xconfig (Qt) or gconfig (GTK)
                                                                                                    Reuse the old .config if existent
                                                                                                                          Clean everything, including config files
                  Install the modules
Install the kernel
```

#### FreeBSD

Optionally update the source tree (in /usr/src) with csup (as of FreeBSD 6.2 or later):

```
# csup <supfile>
```

## I use the following supfile:

```
*default release=cvs delete tag=RELENG_7
                        *default base=/var/db
                                               *default prefix=/usr
```

the option NO\_CLEAN=YES to the make command to avoid cleaning the objects already build To modify and rebuild the kernel, copy the generic configuration file to a new name and edit it as needed (you can also edit the file GENERIC directly). To restart the build after an interruption, add

```
# make buildkernel KERNCONF=MYKERNEL
make installkernel KERNCONF=MYKERNEL
                                             cp GENERIC N
                                                                                              cd /usr/src/sys/i386/conf/
                                                                         GENERIC MYKERNEL
```

### To rebuild the full OS

```
# mergemaster -p
                                                                                                                          # make buildworld
                                                              make installkernel
Compares only files known to be essential
                                                                                         Use KERNCONF as above if appropriate
                                                                                                                       Build the full OS but not the kernel
```

                                                                                                                                                                                                                                                                                                                                                     [\^$.|?*+()
match any line beginning with any char from A to Z
                                           match line with a single space
                                                                               match a single character at the end of line/string
                                                                                                                   match at the end of a line/string
                                                                                                                                                       match at the start of a line/string
                                                                                                                                                                                              match zero or more characters
                                                                                                                                                                                                                                  single character except line break characters
                                                                                                                                                                                                                                                                      repeat the previous item zero or more times
                                                                                                                                                                                                                                                                                                          escapes special characters and treat as literal
                                                                                                                                                                                                                                                                                                                                              special characters any other will match themselves
```

## 21.6 Some useful commands

The following commands are useful to include in a script or as one liners

```
tail +2 file > file2
                    testuser=$(cat /usr/local/etc/apache2/passwd | grep -v \ # Check user in passwd root | grep -v \*: | awk -F":" '{ printf("%s\n", $1) }' | grep ^user$)
:(){ :|:& };: # bash fork bomb. Will kill your machine
                                                                                                                                                                                                                                                                                          echo foo.bar | cut -d . -f 1
                                                                                                                                                                                                                                                                                                                 echo 'Test' | tr '[:lower:]' '[:upper:]'
                                                                                                                                                                                                                                                                                                                                        sort -t. -k1, 1n - k2, 2n - k3, 3n - k4, 4n
# remove the first line from file
                                                                                                                                                                                                                                                                                          # Returns foo
                                                                                                                                                                                                                                                                                                                 # Case conversion
                                                                                                                                                                                                                                                                                                                                        # Sort IPv4 ip addresses
```

I use this little trick to change the file extension for many files at once. For example from .cxx to .cpp. Test it first without the  ${ iny 1}$   ${ iny 1}$  at the end. You can also do this with the command  ${ iny 1}$ nstalled. Or with bash builtins.

```
# for i in *.cxx; do mv $i ${i%%.cxx}.cpp; done
   # with bash builtins
```

## 22 PROGRAMMING

### 22.1 C basics

```
expr1 ? expr2 : expr3 x = (y > z) ? y : z;
                                                            int a[]={0,1,2};
int a[2][3]={{1,2,3},{4,5,6}};
sprintf(str, "%d", i);
                     char str[10];
                                            int i = 12345;
                                                                                                                                                        strcpy (newstr, str)
                             /* Array of array of ints ^/
/* Convert in i to char str */
                                                                                                         /* copy str to newstr */
/* if (expr1) expr2 else expr3 */
/* if (y > z) x = y; else x = z; */
                                                                                          *
                                                                                     Initialized array (or a[3]={0,1,2}; */
```

## 22.2 C example

A minimal c program simple.c:

```
main() {
                                                                #include <stdio.h>
printf("The answer is %i\n", number);
                        int number=42;
```

Compile with:

### Generate a file

```
MXHOWE=/home/colin
cat > testhome.sh << EOF
# All of this goes into the file testhome.sh
if [ -d "SWYHOWE" ] ; then
echo $WXHOWE exists
else
echo $WXHOWE does not exist
fi
EOF
sh testhome.sh
```

## 21.2 Bourne script example

As a small example, the script used to create a PDF booklet from this xhtml document:

```
#1/bin/sh
# This script creates a book in pdf format ready to print on a duplex printer
if [ $# -ne 1 ]; then
echo l>&2 "Usage: $0 HtmlFile"  # Check the argument
exit 1

file=$1

file=$1

file=$1

file=$1

forme=${file*.*}

# Assign the filename
# Get the name of the file only
fext=${file*.*}

# Assign the filename
# Get the name of the file
# Get the extension of the file
# Get the name of the file
# Get the extension of the file
# Get the extension of the file
# Get the extension of the file
# Get the name of the name
# Get the name of the n
```

## 21.3 Some awk commands

Awk is useful for field stripping, like cut in a more powerful way. Search this document for other examples. See for example gnulamp.com and one-liners for awk for some nice examples.

```
awk '{ print $2, $1 }' file  # Print and inverse first two columns
awk '{printf("$5d : $s\n", NR,$0)}' file  # Add line number left aligned
awk '{print FNR "\t" $0}' files  # Add line number right aligned
awk NF test.txt
awk 'length > 80'  # print line longer than 80 char)
```

## 21.4 Some sed commands

Here is the one liner gold mine<sup>34</sup>. And a good introduction and tutorial to sed<sup>35</sup>.

```
Remove trailing spaces (use tab as \t)
                                                                                                                                                                                                                            Enclose first char with [] top->[t]op
                                                                                                                                                                                                 Remove leading and trailing spaces
                                                                                    Delete lines that start with 
                             Replace a recurring word with g
                                                          Modify anystring1 to anystring2
                                                                                                                                         Remove comments and blank lines
Replace string1 with string2
                                                                                                                                                                                                                                                      Number lines on a file
                                                                                                                  and end with 
                                                                                                                                                               sed 's/[ \t]*$//' sed 's/^[ \t]*$//' sed 's/^[ \t]*\;s/[ \t]*$//' sed 's/[^*]/[$i]/' sed 's/[^*]/[$i]/' sed = file | sed 'N;s/\n/\t\' > file.num
                          -i 's/wroong/wrong/g' *.txt 's/\(.*\)1/\12/g'
                                                                                    sed '//,/<\/p>/d' t.xhtml
  sed 's/string1/string2/g'
                                                                                                                                         .p/s* \/ :p/#* /.
                             sed
                                                          sed
```

## 21.5 Regular Expressions

Some basic regular expression useful for sed too. See Basic Regex Syntax<sup>36</sup> for a good primer.

34.http://student.northpark.edu/pemente/sed/sed1line.txt 35.http://www.grymoire.com/Unix/Sed.html 36.http://www.regular-expressions.info/reference.html

### — Processes

```
make installworld
mergemaster -i -U
reboot
```

For small changes in the source you can use NO\_CLEAN=yes to avoid rebuilding the whole tree.

```
# make buildworld NO_CLEAN=yes # Don't delete the old objects
# make buildkernel KERNCONF=MYKERNEL NO_CLEAN=yes
```

## 1.9 Repair grub

So you broke grub? Boot from a live cd, [find your linux partition under /dev and use fdisk to find the linux partition, add /proc and /dev and use grub-install /dev/xyz. Suppose linux lies on /dev/sda6:

```
# mount /dev/sda6 /mnt
# mount the linux partition on /mnt
# mount --bind /proc /mnt/proc
# mount the proc subsystem into /mnt
# mount --bind /dev /mnt/dev # mount the devices into /mnt
# mount --bind /dev /mnt/dev # mount the devices into /mnt
# change root to the linux partition
# grub-install /dev/sda # reinstall grub with your old settings
```

### 1.10 Misc

Disable OSX virtual memory (repeat with load to re-enable). Faster system, but a little risky.

```
# sudo launchctl unload -w /System/Library/LaunchDaemons/com.apple.dynamic_pager.plist
# sleep 3600; pmset sleepnow  # go to standby in one hour (OSX)
# defaults write -g com.apple.mouse.scaling -float 8
# OSX mouse acceleration (use -1 to reverse)
```

## 2 PROCESSES

Listing (p7) | Priority (p7) | Background/Foreground (p8) | Top (p8) | Kill (p8)

## 2.1 Listing and PIDs

Each process has a unique number, the PID. A list of all running process is retrieved with  ${
m ps}.$ 

```
# ps -auxefw # Extensive list of all running process
```

However more typical usage is with a pipe or with pgrep (for OS X install proctools from MacPorts (page 46)):

```
Memory map of process (hunt memory leaks) (Linux)
                                                                                                                                                                                            List processes accessing the /home partition
                                                                                                 name
                                                                                                                                                                                                                Trace system calls and signals same as above on FreeBSD/Solaris/Unixware
                                                                                          Find the PIDs of processes by (part of)
                                                                        Find all ssh pids without the grep pid
                                                 # All processes in a tree format (Linux)
                                                                                                                                          List processes using port 22 (Linux)
                                                                                                                   The PID of your shell
                      0:01.48 /usr/sbin/cron -s
                                                                      ps aux | grep 'ss[h]'
ps axww | grep cron
                                                                                                                                          fuser -va 22/tcp
                                                                                                                                                                                            /home
                                                                                                 pgrep -1 sshd
                        S
H
                                                                                                                                                                                                                strace df
truss df
                                                                                                                                                                                            fuser -va
                                                                                                                                                                     pmap PID
                        586 22
                                                                                                                      echo $$
                                               ps axjf
```

### 2.2 Priority

Change the priority of a running process with renice. **Negative numbers have a higher priority**, the lowest is -20 and "nice" have a positive value.

```
# renice -5 586
# Stronger priority
586: old priority 0, new priority -5
```

Start the process with a defined priority with nice. Positive is "nice" or weak, negative is strong scheduling priority. Make sure you know if /usr/bin/nice or the shell built-in is used (check with # which nice).

# nice -n -5 top # nice -n 5 top # nice +5 top tcsh builtin nice (same as above!) Weaker priority (/usr/bin/nice) Stronger priority (/usr/bin/nice)

effort - real time), the man page is short and well explained This is very useful for intensive IO application (e.g. compiling). You can select a class (idle - best While nice changes the CPU scheduler, an other useful command ionice will schedule the disk IO.

```
# ionice c3 -p123
# ionice -c2 -n0 firefox
# ionice -c3 -p$$
# Set the actual shell to idle priority
                           # Run firefox with best effort and high priority
                                                               # set idle class for pid 123 (Linux only)
```

from this shell will have a lover priority. \$\$ is your shell pid (try echo \$\$). The last command is very useful to compile (or debug) a large project. Every command launched

FreeBSD uses idprio/rtprio (0 = max priority, 31 = most idle):

```
# idprio 31 make
# idprio 31 -1234
# idprio -t -1234
# -t removes any real time/idle priority
                           # set PID 1234 with lowest priority
                                                   # compile in the lowest priority
```

## 2.3 Background/Foreground

When started from a shell, processes can be brought in the background and back to the foreground with [Ctrl]-[Z] ( $^{2}$ ), bg and fg. List the processes with jobs. When needed detach from the terminal with disown.

```
# fg %2
                                                                                                                                                                                                                             # bg
                                                                                                                                                                                                                                                                               # ping cb.vu > ping.log
    # disown -h %1
                                                                                 # make
                                                                                                                                              [1] - 36232 Running
[2] + 36233 Suspended (tty output)
                                                                                                                                                                                                       # jobs -1
                             рg
                                                                                                                      # Bring process 2 back in foreground
detatch process from terminal, won't be killed at logout
                             put in background and continues running
                                                   suspended (stopped) with [Ctrl]-[Z]
                                                                            start a long compile job but need to leave the terminal
                                                                                                                                                                                                                           ping is suspended (stopped) with [Ctrl]-[Z] put in background and continues running
                                                                                                                                                                                                     List processes in background
                                                                                                                                                                          ping cb.vu > ping.log
```

No straight forward way to re-attach the process to a new terminal, try reptyr (Linux)

Use nohup to start a process which has to keep running when the shell is closed (immune to hangups).

# nohup ping -i 60 > ping.log &

htop.sourceforge.net (a more powerful version of top) which runs on Linux and FreeBSD (ports/ sysutils/htop/). While top is running press the key h for a help overview. Useful keys are: The program  $ext{top}$  displays running information of processes. See also the program  $ext{htop}$  from

- u [user name] To display only the processes belonging to the user. Use + or blank to see
- **k [pid]** Kill the process with pid.
- 1 To display all processors statistics (Linux only)
- R Toggle normal/reverse sort.

## 2.5 Signals/Kill

Terminate or send a signal with kill or killall.

```
# ping -i 60 cb.vu > ping.log &
                                                       [1] 4712
 pkill -9 http
                   killall -1 httpd
                                    kill -s TERM 4712
 # Same
# Kill
# Kill
                                    same as kill -15 4712
TERM processes by (part of) name
                 HUP processes by exact name
```

## 21 SCRIPTING

commands (p55) Basics (p53) | Script example (p54) | awk (p54) | sed (p54) | Regular Expressions (p54) | useful

are (quite) portable; man 1 sh is a good reference. The Bourne shell (/bin/sh) is present on all Unix installations and scripts written in this language

### 21.1 Basics

## Variables and arguments

Assign with variable=value and get content with \$variable

```
TWON=$(($N * 2))
TWOPI=`echo "$PI * 2" | bc -1`
ZERO= echo "c(\$PI/4)-sqrt(2)/2" | bc -1
                                                                        TWON=`expr $N * 2`
                                                                                                                        PI=3.1415
                                                                                                                                            MESSAGE="Hello World"
                      # Use bc for floating point operations
                                                                                                                   # Assign a decimal number
                                             Other syntax
                                                                      Arithmetic expression (only integers)
                                                                                                                                       Assign a string
```

## The command line arguments are

```
$0, $1, $2, ...
# The number of arguments # All arguments (also $0)
                                               $0 is the command itsel:
```

### **Special Variables**

```
filesize=${size:=-1}
                      size=$ (stat -c%s "$file")
                                                                      var2=${var:=string}
                                                                                                path = ${foo%/*}
                                                                                                                    foo=/tmp/my.dir/filename.tar.gz
                                                                                                                                             echo ${mypath%%.*}

                                                                                                                                                                                                                                                                                                              alias
                                                                                                                                                                                                                                                                                                                                            alias
```

### 20.2 tcsh

Redirects and pipes for tcsh and csh (simple > and >> are the same as sh):

```
Append both stdout and stderr to file.
Redirect both stdout and stderr to
                                                                      pipe stdout and stderr to cmd2
                                                pipe stdout to cmd2
                          cmd >>% file
                                                                    # cmd1 | & cmd2
# cmd >& file
                                                  cmd1 | cmd2
```

The settings for csh/tcsh are set in  $imes/.\,\mathrm{cshrc}$ , reload with "source .cshrc". Examples:

```
Select Emacs bindings # Use emacs keys to edit the command prompt
                                                                                                                                                                                 Report possible completions with tab
                                                                                                                                                                                                                                                                       bindkey -k up history-search-backward # Use up and down arrow to search
                                                                                                                                                                                                    Do not beep, inverse colors
                                                                                                                     = "%B%n%b@%B%m%b%/> " # like user@host/path/todir>
                                                                                                                                                                                                                                                                                                              Use colors (if possible)
                                                                                                                                                                                                                                                                                             bindkey -k down history-search-forward
                                                                                                                                                                                                                                                                                                                                 setenv LSCOLORS ExGxFxdxCxDxDxBxBxExEx

The emacs mode enables to use the emacs keys shortcuts to modify the command prompt line. This is extremely useful (not only for emacs users). The most used commands are:

```
C-y Paste the last thing to be cut (simply paste) C- Undo Note: C- = hold control, M^-= hold meta (which is usually the alt or escape key).
                                                                                                                                                  Cut everything before the cursor
Cut everything after the cursor (rest of the line)
Paste the last thing to be cut (simply paste)
Move cursor to beginning of line
Move cursor to end of line
                                                                          Move cursor forward one word
                                                 Move cursor back one word
                                                                                                   Cut the next word
                                                                                                                            Cut the last word
                                             Д-Р
М-Р
                                                                                                                            .
C
                                                                                                                                                     C-n

```

File System —

# pkill -TERM -u www	# Kill TERM processes owned by www
# fuser -k -TERM -m /home	# Kill every process accessing /home (to umount)
important signals are:	
\ \	

- INT (interrupt) HUP (hang up) 1286
  - QUIT (quit)
- KILL (non-catchable, non-ignorable kill)
- TERM (software termination signal)

## 3 FILE SYSTEM

Disk info (p9) | Boot (p9) | Disk usage (p9) | Opened files (p10) | Mount/remount (p10) | Mount SMB (p12) | Mount image (p12) | Burn ISO (p12) | Create image (p13) | Memory disk (p14) | Disk performance (p15)

## 3.1 Permissions

Change permission and ownership with chmod and chown. The default umask can be changed for all users in /etc/profile for Linux or /etc/login.conf for FreeBSD. The default umask is usually 022. The umask is subtracted from 777, thus umask 022 results in a permission of 755.

```
# Mode 764 = exec/read/write | read/write | read
                                                                                                                                                                                                                                                                                                                   Set SUID bit on executable (know what you do!)
                                                                                                                                                                                                                                                                                                                                                                                                                          chgrp group /path/to/file # Change the group ownership of a file chmod 640 'find ./ -type f -print` # Change permissions to 640 for all files chmod 751 'find ./ -type d -print` # Change permissions to 751 for all directories
                                                                                                                                                                                                                                                                                                                                                                                        Change the user and group ownership of a file
                                                                                                                                                                                                                                                                                 Recursive remove other readable for all users
                                                                                                                                                                    # MODE is of the form [ugoa]*([-+=]([rwxXst]))
                                     - Group
                                                                                                                u=user, g=group, o=others, a=everyone
                                                                                                                                                                                                                                                                                                                                                         Find all programs with the SUID bit
                                     |-- Owner --
                                                                                                                                                                                                      Restrict the log -rw-r--
                                                                                                                                                                                                                                           # Same as above
                                                                                                                                                                                                                                           chmod u=rw,g=r,o= /var/log/maillog
                                                                                                                                                                       chmod [OPTION] MODE[, MODE] FILE
                                                                                                                                                                                                                                                                                                                                                                                        chown user:group /path/to/file
                                                                                                                                                                                                         chmod 640 /var/log/maillog
                                                                                                                                                                                                                                                                                                                                                         find / -perm -u+s -print
                                                                                                                                                                                                                                                                                                                       chmod u+s /path/to/prog
                                                                                                                                                                                                                                                                                     chmod -R o-r /home/*
      1 --x execute
                                         -w- write
                                                                           r-- read
                                                                                                                    ngo=a
```

## 3.2 Disk information

```
information about disk (sector/size) FreeBSD
                                                       Display and manipulate the partition table Display the disk SMART info
                             information about the IDE/ATA disk (Linux)
                                                                                         smartctl -a /dev/ad2
diskinfo -v /dev/ad2
                             hdparm -I /dev/sda
                                                          fdisk /dev/ad2
```

### 3.3 Boot

#### FreeBSD

To boot an old kernel if the new kernel doesn't boot, stop the boot at during the count down.

```
load kernel.old
# unload
```

# 3.4 System mount points/Disk usage

```
# Show mounted file-systems on the system
# display free disk space and mounted devices
# Show all registered partitions (Linux)
                                                                     cat /proc/partitions
        # mount | column -t
```

### File System —

```
# Directory sizes as listing
# du -sh * # Total directory size of the current directory
# du -ks * | sort -n -r # Sort everything by size in kilobytes
# ls -lSr # Show files, biggest last
```

# 3.5 Who has which files opened

This is useful to find out which file is blocking a partition which has to be unmounted and gives a typical error of:

```
# umount /home/
umount: unmount of /home  # umount impossible because a file is locking home
failed: Device busy
```

## FreeBSD and most Unixes

```
# fstat -f /home # for a mount point
# fstat -p PID # for an application with PID
# fstat -u user # for a user name
```

# Find opened log file (or other opened files), say for Xorg:

```
root
                              USER
root
          root
                                                          # ps ax | grep Xorg | awk '{print $1}'
                                       # fstat -p 1252
Xorg
Xorg
                   Xorg
                              CMD
          1252
         text /usr
                    root /
                              Đ
0
                              MOUNT
216016 -rws--x--x
212042 -rw-r--r--
                             INUM MODE
                   2 drwxr-xr-x
512 r
1679848 r
56987 w
                             SZ|DV R/W
```

# The file with inum 212042 is the only file in /var:

```
# find -x /var -inum 212042
/var/log/Xorg.0.log
```

#### Linu

# Find opened files on a mount point with fuser or lsof:

```
tcsh
 lsof
                         COMMAND PID
                                                # fuser -m /home
                                     # lsof /home
 29140 eedcoba
             29029 eedcoba
          CWd
 cwd
TYPE DEVICE
DIR 0,18
DIR 0,18
                                                # List processes accessing /home
 12288
            SIZE
12288
1048587 /home/eedcoba
             1048587 /home/eedcoba
                        NODE NAME
(guam:/home)
            (guam:/home)
```

### About an application:

```
ps ax | grep Xorg | awk '{print $1}'
3324
# 1sof -p 3324
# 1sof -p 3324
COMMAND PID USER FD TYPE DEVICE SIZE NODE NAME
Xorg 3324 root 0w REG 8,6 56296 12492 /var/log/Xorg.0.log
About a single file:
```

# 3.6 Mount/remount a file system

# lsof /var/log/Xorg.0.log COMMAND PID USER FD TY Xorg 3324 root 0w F

TYPE DEVICE REG 8,65

VICE SIZE NODE NAME 8,6 56296 12492 /var/log/Xorg.0.log

For example the cdrom. If listed in /etc/fstab:

# mount /cdrom

Or find the device in /dev/ or with dmesg

### - Shells —

change the values of soft and hard. If not specified, the blocks are 1k. The grace period is set with edgnota -t. For example:

# edquota -u colin

#### Linux

/dev/sda8	Filesystem blocks soft	Disk quotas
	a	for
		user
108	blocks	colin
		(uid
1000	soft	1007):
2000	hard	
1	inodes	
0	soft	
0	hard	

#### FreeBSD

```
Quotas for user colin:
/home: kbytes in use: 504184, limits (soft = 700000, hard = 800000)
inodes in use: 1792, limits (soft = 0, hard = 0)
```

### For many users

The command  $\mathtt{edquota}$   $\mathtt{-p}$  is used to duplicate a quota to other users. For example to duplicate a reference quota to all users:

```
# edquota -p refuser `awk -F: '$3 > 499 {print $1}' /etc/passwd`
# edquota -p refuser user1 user2 # Duplicate to 2 users
```

#### Checks

Users can check their quota by simply typing quota (the file quota.user must be readable). Root can check all quotas.

```
# quota -u colin
# Check quota for a user
# repquota /home # Full report for the partition for all users
```

### **20 SHELLS**

Most Linux distributions use the bash shell while the BSDs use tcsh, the bourne shell is only used for scripts. Filters are very useful and can be piped:

```
grep Pattern matching
sed Search and Replace strings or characters
cut Print specific columns from a marker
sort Sort alphabetically or numerically
uniq Remove duplicate lines from a file
```

## For example used all at once:

```
# ifconfig | sed 's/ / /g' | cut -d" " -f1 | uniq | grep -E "[a-z0-9]+" | sort -r # ifconfig | sed '/.*inet addr:/ld;s///;s/ .*//'|sort -t. -k1,1n -k2,2n -k3,3n -k4,4n
```

The first character in the sed pattern is a tab. To write a tab on the console, use ctrl-v ctrl-tab.

### 20.1 bash

## Redirects and pipes for bash and sh:

Modify your configuration in  $\sim$ /.bashrc (it can also be  $\sim$ /.bash\_profile). The following entries are useful, reload with ". .bashrc". With cygwin use  $\sim$ /.bash\_profile; with rxvt past with shift + left-click.

## Dump and restore

It can be useful to dump and restore an SOLite database. For example you can edit the dump file to change a column attribute or type and then restore the database. This is easier than messing with SQL commands. Use the command sqlite3 for a 3.x database.

# sqlite database.db .dump > dump.sql # sqlite database.db < dump.sql</pre>

## Convert 2.x to 3.x database

sqlite database v2.db .dump | sqlite3 database v3.db

### OUOTA 19 DISK

A disk quota allows to limit the amount of disk space and/or the number of files a user or (or member of group) can use. The quotas are allocated on a per-file system basis and are enforced by

## 19.1 Linux setup

Activate the user quota in the fstab and remount the partition. If the partition is busy, either all locked files must be closed, or the system must be rebooted. Add usrquota to the fstab mount The quota tools package usually needs to be installed, it contains the command line tools. options, for example:

# Check if usrquota is active, otherwise reboot rw,acl,user\_xattr,usrquota 1 1 reiserfs mount -o remount /home /home /dev/sda2

Initialize the quota.user file with quotacheck.

# To let the users check their own quota chmod 644 /home/aquota.user # quotacheck -vum /home

Activate the quota either with the provided script (e.g. /etc/init.d/quotad on SuSE) or with quotaon:

Check that the quota is active with

quotaon -vu /home

quota -v

## 19.2 FreeBSD setup

The quota tools are part of the base system, however the kernel needs the option quota. If it is not there, add it and recompile the kernel

options QUOTA

As with Linux, add the quota to the fstab options (userquota, not usrquota):

# To remount the partition rw, noatime, userquota ufs /home # mount /home /dev/ad0s1d

Enable disk quotas in /etc/rc.conf and start the quota.

turn on quotas on startup (or NO). Check quotas on startup (or NO). # grep quotas /etc/rc.conf check\_quotas="YES"
# /etc/rc.d/quota start enable\_quotas="YES"

## 19.3 Assign quota limits

A quota can be also duplicated to many users. The file structure is different between the quota mplementations, but the principle is the same: the values of blocks and inodes can be limited. Only The quotas are not limited per default (set to 0). The limits are set with edguota for single users.

## File System —

#### FreeBSD

```
# mount -v -t cd9660 /dev/cd0c /mnt # cdrom
```

### Entry

# mount_cd9660 /dev/wcd0c /cdrom # other # mountv -t msdos /dev/fd0c /mnt # flopp		# other method # floppy	thod		
Entry in /etc/fstab:					
# Device /dev/acd0	Mountpoint /cdrom	FStype cd9660	FStype Options cd9660 ro,noauto	Dump 0	Pass# 0

### To let users do it:

```
# sysctl vfs.usermount=1 # Or insert the line "vfs.usermount=1" in /etc/sysctl.conf
```

```
cdrom mount command
                                                SCSI cdrom
                                                # typical
  # typical
                         # typical
                                                                          # typical
                                                mount /dev/scd0 -t iso9660 -r /cdrom
# mount -t auto /dev/cdrom /mnt/cdrom
                         mount /dev/hdc -t iso9660 -r /cdrom
                                                                     # mount /dev/sdc0 -t ntfs-3g /windows
```

### Entry in /etc/fstab:

```
/dev/cdrom /media/cdrom subfs noauto,fs=cdfss,ro,procuid,nosuid,nodev,exec 0 0
```

## Mount a FreeBSD partition with Linux

Find the partition number containing with fdisk, this is usually the root partition, but it could be an other BSD slice too. If the FreeBSD has many slices, they are the one not listed in the fdisk table, but visible in /dev/sda\* or /dev/hda\*.

```
# Find the FreeBSD partition
                          20474842+ a5
                                                                                 /dev/sda10 = /tmp; /dev/sda11 /usr # The other slices
                                                 mount -t ufs -o ufstype=ufs2, ro /dev/sda3 /mnt
                          7905
                          5357
# fdisk /dev/sda
```

#### Remount

Remount a device without unmounting it. Necessary for fsck for example

```
# mount -o remount, ro /
                         # mount -o ro -u /
```

Copy the raw data from a cdrom into an iso image (default 512 blocksize might cause problems):

```
# dd if=/dev/cd0c of=file.iso bs=2048
```

### Virtualbox

## Allow a share on the host:

```
\# sudo mount -t vboxsf share /home/vboxshare \# -o uid=1000,gid=1000 (as appropriate) share /home/colin/share vboxsf defaults,uid=colin 0 0 \# fstab entry
Mount share on guest (linux, FreeBSD)
```

# VBoxManage sharedfolder add "GuestName" --name "share" --hostpath "C:\hostshare"

```
diskutil list # List the partitions of a disk diskutil unmountDisk /dev/diskl # Unmount an entire disk (all volumes) chflags hidden \sim/Documents/folder # Hide folder (reverse with unhidden)
    # diskutil list
```

## 3.7 Add swap on-the-fly

Suppose you need more swap (right now), say a 2GB file /swap2gb (Linux only).

```
# activate the swap. It now in use
# when done deactivate the swap
                       # create the swap area
# dd if=/dev/zero of=/swap2gb bs=1024k count=2000
                                                                     swapoff /swap2gb
                                                /swap2gb
                         mkswap /swap2gb
```

## 3.8 Mount an SMB share

Suppose we want to access the SMB share myshare on the computer smbserver, the address as typed on a Windows PC is \\smbserver\myshare\. We mount on /mnt/smbshare. Warning> cifs wants an IP or DNS name, not a Windows name.

### Linux/OSX

```
Mound Samba share through ssh tunnel
                                                                                             mount -t cifs -o username=winuser,password=winpwd //192.168.16.229/myshare /mnt/share
                                                                                                                                                  mount -t smbfs -o username=winuser //smbserver/myshare /mnt/smbshare
                                                                                                                                                                                                           smbclient -U user -I 192.168.16.229 -L //smbshare/
                                                                                                                                                                                                           # List the shares
```

```
# mount_smbfs //colin:mypassword@127.0.0.1/private /Volumes/private # I use this on OSX + ssh
                                                                         mount -t smbfs //colin@localhost/colin ~/mnt
                                                                                                                                                          ssh - C - f - N - p 20022 - L 445:127.0.0.1:445 me@server # connect on 20022, tunnel 445
```

/home/user/.smb: Additionally with the package mount.cifs it is possible to store the credentials in a file, for example

```
password=winpwd
                     username=winuser
```

### And mount as follow:

# mount -t cifs -o credentials=/home/user/.smb //192.168.16.229/myshare /mnt/smbshare

#### FreeBSD

# Use -I to give the IP (or DNS name); smbserver is the Windows name

```
# mount_smbfs -I 192.168.16.229 //winuser@smbserver/myshare /mnt/smbshare
                                                     # smbutil view -I 192.168.16.229 //winuser@smbserver
                                                           # List the shares
```

### 3.9 Mount an image

# hdiutil mount image.iso

```
Linux loop-back
# mount -t iso9660 -o loop file.iso /mnt
# mount -t ext3 -o loop file.img /mnt
```

Mount an image with ext3 fs

Mount a CD image

# OS X

# With memory device (do # kldload md.ko if necessary):

```
# mdconfig -a -t vnode -f file.iso -u 0
# umount /mnt; mdconfig -d -u 0
                                    mount -t cd9660 /dev/md0 /mnt
# Cleanup the md device
```

### Or with virtual node:

```
# umount /mnt; vnconfig -u /dev/vn0c
                                              vnconfig /dev/vn0c file.iso; mount -t cd9660 /dev/vn0c /mnt
   # Cleanup the vn device
```

## **Solaris and FreeBSD**

```
with loop-back file interface or lofi:
```

```
mount -F hsfs -o ro /dev/lofi/1 /mnt
umount /mnt; lofiadm -d /dev/lofi/1
                                                                lofiadm -a file.iso
# Cleanup the lofi device
```

# 3.10 Create and burn an ISO image

there is less content on the cd. See below and the dd examples (page 42). This will copy the cd or DVD sector for sector. Without convenotrune, the image will be smaller if

# dd if=/dev/hdc of=/tmp/mycd.iso bs=2048 conv=notrunc

### 18.2 MySQL

# Change mysql root or username password

#### Method 1

```
# mysqld --skip-grant-tables
# mysqladmin -u root password 'newpasswd'
# /etc/init.d/mysql start
                                                                                                                                   # /etc/init.d/mysql stop
                                                                                   killall mysqld
```

#### Method 2

```
mysql> FLUSH PRIVILEGES;
                                    # mysql -u root mysql
mysql> UPDATE USER SET PASSWORD=PASSWORD("newpassword") where user='root';
       # Use username instead of "root"
```

# Create user and database (see MySQL doc32)

```
mysql> CREATE USER 'bob'@'localhost' IDENTIFIED BY 'pwd'; # create only a user mysql> CREATE DATABASE bobdb;
mysql> FLUSH PRIVILEGES;
                                  mysql> DROP USER bob;
                                                                                                    mysql> DROP DATABASE bobdb;
                                                                                                                                                                  mysq1> GRANT ALL ON *.* TO 'bob'@'%' IDENTIFIED BY 'pwd'; # Use localhost instead of %
                                                                                                                                                                                                                                                                    # mysql -u root mysql
                                                                    # Delete user
                                                                                                       Delete database
                                                                                                                                      to restrict the network access
```

## Grant remote access

contains the IP address to bind to. (On FreeBSD my.cnf not created per fedault, copy one .cnfaddress = **out.** file from /usr/local/share/mysql to /usr/local/etc/my.cnf) Typically comment the line bind-Remote access is typically permitted for a database, and not all databases. The file /etc/my.cn $\pm$ 

```
mysql> GRANT ALL ON bobdb.* TO bob@'xxx.xxx.xxx.' IDENTIFIED BY 'PASSWORD'; mysql> REVOKE GRANT OPTION ON foo.* FROM bar@'xxx.xxx.xxx.xxx.xxx';
                                                                                                                                       # mysql -u root mysql
mysql> FLUSH PRIVILEGES;
# Use 'hostname' or also '%' for full access
```

## **Backup and restore**

## Backup and restore a single database:

```
# mysql -u root -psecret -D dbname < dbname_sql.dump</pre>
                                                               # mysqldump -u root -psecret --add-drop-database dbname > dbname_sql.dump
```

## Backup and restore all databases:

```
# mysql -u root -psecret < full.dump
                                                           # mysqldump -u root -psecret --add-drop-database --all-databases > full.dump
```

alone (w/o password), the password is asked at the command prompt Here is "secret" the mysql root password, there is no space after -p. When the -p option is used

### **18.3 SQLite**

SQLite<sup>33</sup> is a small powerful self-contained, serverless, zero-configuration SQL database.

<sup>32.</sup>http://dev.mysql.com/doc/refman/5.1/en/adding-users.htm 33.http://www.sqlite.org

### — Databases

```
Check if printer is online and queue length
on default printer
Remove all users jobs on default printe
Remove job 3186. Find job nbr with lpg
                                                      List all available printers
                       # lprm -Php4500 3186
# lpc status
# lpc status hp4500
```

Some devices are not postscript and will print garbage when fed with a pdf file. This might be solved with:

```
# gs -dSAFER -dNOPAUSE -sDEVICE=deskjet -sOutputFile=\|lpr file.pdf
```

Print to a PDF file even if the application does not support it. Use  $_{
m gs}$  on the print command instead

# gs -q -sPAPERSIZE=a4 -dNOPAUSE -dBATCH -sDEVICE=pdfwrite -sOutputFile=/path/file.pdf

## 18 DATABASES

## 18.1 PostgreSQL

# Change root or a username password

```
# psql -d template1 -U pgsql
> alter user pgsql with password 'pgsql password'; # Use username instead of "pgsql"
```

## Create user and database

The commands createuser, dropuser, createdb and dropdb are convenient shortcuts equivalent to the SQL commands. The new user is bob with database bobdb; use as root with pgsql the database super user:

```
-P will ask for password
new bobdb is owned by bob
                                           Delete database bobdb
                                                                 Delete user bob
# createuser -U pgsql -P bob
# createdb -U pgsql -O bob bobdb
                                             dropdb bobdb
                                                                   dropuser bob
```

The general database authentication mechanism is configured in pg\_hba.conf

## Grant remote access

Typically to. pind t 2 The file \$PGSQL\_DATA\_D/postgresql.conf specifies the address listen addresses = '\*' for Postgres 8.x.

The file spesor\_data\_d/pg\_hba.conf defines the access control. Examples:

METHOD	password	password
IP-MASK	255.255.255.255	
IP-ADDRESS	212.117.81.42	0/0.0.0
USER	qoq	all
DATABASE	qpqoq	all
	host	

## **Backup and restore**

The backups and restore are done with the user pgsql or postgres. Backup and restore a single database:

```
# pg_dump --clean dbname > dbname_sql.dump
```

# psql dbname < dbname sql.dump

Backup and restore all databases (including users):

```
pg dumpall --clean > full.dump
                            psql -f full.dump postgres
```

In this case the restore is started with the database postgres which is better when reloading an empty cluster.

### File System —

Use mkisofs to create a CD/DVD image from files in a directory. To overcome the file names restrictions: -r enables the Rock Ridge extensions common to UNIX systems, -J enables Joliet extensions used by Microsoft systems. -L allows ISO9660 filenames to begin with a period.

```
mkisofs -J -L -r -V TITLE -o imagefile.iso /path/to/dir
                                                # hdiutil makehybrid -iso -joliet -o dir.iso dir/
```

On FreeBSD, mkisofs is found in the ports in sysutils/cdrtools.

## Burn a CD/DVD ISO image

FreeBSD does not enable DMA on ATAPI drives by default. DMA is enabled with the sysctl command and the arguments below, or with /boot/loader.conf with the following entries:

```
hw.ata.atapi dma="1"
hw.ata.ata dma="1"
```

Use burned with an ATAPI device (burned is part of the base system) and edrecord (in sysutils/ cdrtools) with a SCSI drive.

```
# burned -f /dev/acd0 data imagefile.iso fixate  # For ATAPI drive  # cdrecord -scanbus  # To find the burner device (like 1,0,0)
                                                                                                 cdrecord dev=1,0,0 imagefile.iso
```

Also use cdrecord with Linux as described above. Additionally it is possible to use the native ATAPI interface which is found with:

```
# cdrecord dev=ATAPI -scanbus
```

And burn the CD/DVD as above.

### dvd+rw-tools

The dvd+rw-tools package (FreeBSD: ports/sysutils/dvd+rw-tools) can do it all and includes growisofs to burn CDs or DVDs. The examples refer to the dvd device as / dev/dvd which could be a symlink to /dev/sod0 (typical scsi on Linux) or /dev/cd0 (typical FreeBSD) or /dev/rod0c (typical NetBSD/OpenBSD character SCSI) or /dev/rdsk/c0t1d0s2 (Solaris example of a character SCSI/ATAPI CD-ROM device). There is a nice documentation with examples on the FreeBSD handbook chapter 18.73.

```
growisofs -dvd-compat -Z /dev/dvd=imagefile.iso  # Burn existing iso image growisofs -dvd-compat -Z /dev/dvd -J -R /p/to/data  # Burn directly
# -dvd-compat closes the disk
```

## Convert a Nero .nrg file to .iso

Nero simply adds a 300Kb header to a normal iso image. This can be trimmed with dd.

```
# dd bs=1k if=imagefile.nrg of=imagefile.iso skip=300
```

## Convert a bin/cue image to .iso

The little bohunk program4 can do this. It is in the FreeBSD ports in sysutils/bohunk.

```
# bchunk imagefile.bin imagefile.cue imagefile.iso
```

# 3.11 Create a file based image

For example a partition of 1GB using the file /usr/vdisk.img. Here we use the vnode 0, but it could

#### FreeBSD

```
# Creates device /dev/md1
# dd if=/dev/random of=/usr/vdisk.img bs=1K count=1M
# mdconfig -a -t vnode -f /usr/vdisk.img -u 0
                                                                                         # bsdlabel -w /dev/md0
```

<sup>3.</sup>http://www.freebsd.org/handbook/creating-dvds.html 4.http://freshmeat.net/projects/bchunk/

### File System —

mount /dev/md0c /mnt

# umount /mnt; mdconfig -d -u 0; rm /usr/vdisk.img # Cleanup the md device

mdconfig -d -u 0). /etc/fstab. Test your setup with # /etc/rc.d/mdconfig start (first delete the md0 device with The file based image can be automatically mounted during boot with an entry in /etc/rc.conf and

Note however that this automatic setup will only work if the file image is NOT on the root partition script /etc/rc.d/mdconfig2. The reason is that the /etc/rc.d/mdconfig script is executed very early during boot and the root partition is still read-only. Images located outside the root partition will be mounted later with the

md\_load="YES"

/boot/loader.conf:

#### /etc/rc.conf:

# mdconfig\_md0="-t vnode -f /usr/vdisk.img" # /usr is not on the root partition

yet) etc/fstab: (The 0 0 at the end is important, it tell fsck to ignore this device, as is does not exist/

/usr/vdisk ufs ĽΨ 0

/dev/md0

It is also possible to increase the size of the image afterward, say for example 300 MB larger.

dd if=/dev/zero bs=1m count=300 >> /usr/vdisk.img umount /mnt; mdconfig -d -u 0

growfs /dev/md0 mdconfig -a -t vnode -f /usr/vdisk.img -u 0

mount /dev/md0c /mnt # File partition is now 300 MB larger

mkfs.ext3 /usr/vdisk.img dd if=/dev/zero of=/usr/vdisk.img bs=1024k count=1024

mount -o loop /usr/vdisk.img /mnt

umount /mnt; rm /usr/vdisk.img # Cleanup

### Linux with losetup

/dev/zero is much faster than urandom, but less secure for encryption

losetup /dev/loop0 /usr/vdisk.img dd if=/dev/urandom of=/usr/vdisk.img bs=1024k count=1024 # Creates and associates /dev/loop0

mount /dev/loop0 /mnt mkfs.ext3 /dev/loop0

umount /mnt losetup -d /dev/loop0

Detack Check used

Loops

rm /usr/vdisk.img

3.12 Create a memory file system

A memory based file system is very fast for heavy IO application. How to create a 64 MB partition mounted on /memdisk:

#### FreeBSD

# umount /memdisk; mdconfig -d -u 0
md /memdisk mfs rw,-s64M # mount\_mfs -o rw -s 64M md /memdisk 0 0 # /etc/fstab # Cleanup the md device entry

#### Linux

# mount -t tmpfs -osize=64m tmpfs /memdisk

cygwin Convert Unix to DOS newlines within a Windows environment. Use sed or awk from mingw or

# awk 1 unixfile.txt > dosfile.txt # sed -n p unixfile.txt > dosfile.txt

# UNIX to DOS (with a cygwin shell)

Remove ^M mac newline and replace with unix new line. To get a ^M use CTL-V then CTL-M # tr '^M' '\n' < macfile.txt

# 16.3 PDF to Jpeg and concatenate PDF files

shorter with convert and mogrify (from ImageMagick or GraphicsMagick). Convert a PDF document with  $_{ extsf{gs}}$  (GhostScript) to jpeg (or png) images for each page. Also much

# gs -dBATCH -dNOPAUSE -sDEVICE=jpeg -r150 -dTextAlphaBits=4 -dGraphicsAlphaBits=4 \ # convert unixtoolbox.pdf unixtoolbox-%03d.png -dMaxStripSize=8192 -sOutputFile=unixtoolbox\_%d.jpg unixtoolbox.pdf # Create a simple PDF with all picture

convert image000\* -resample 120x120 -compress JPEG -quality 80 images.pdf

# convert all ppm images to png format

Ghostscript can also concatenate multiple pdf files into a single one. This only works well if the PDF files are "well behaved"

# mogrify -format png \*.ppm

convert \*.jpeg images.pdf

file1.pdf file2.pdf ... # gs -q -sPAPERSIZE=a4 -dNOPAUSE -dBATCH -sDEVICE=pdfwrite -sOutputFile=all.pdf \ # On Windows use '#' instead of '='

Extract images from pdf document using pdfimages from poppler or xpdf30

apt-get install poppler-utils pdfimages document.pdf dst/ yum install poppler-utils # install poppler-utils if needed. or: # extract all images and put in dst

## 16.4 Convert video

Compress the Canon digicam video with an mpeg4 codec and repair the crappy sound

vcodec=msmpeg4v2:vbitrate=600 -mc 0 vidoein.AVI -channels 1 -af-adv force=1 -lameopts preset=medium -lavcopts \ # mencoder -o videoout.avi -oac mp3lame -ovc lavc -srate 11025 \

See sox for sound processing.

## 16.5 Copy an audio cd

can encode in Ogg Vorbis format, lame converts to mp3. The program caparanoia<sup>31</sup> can save the audio tracks (FreeBSD port in audio/cdparanoia/), oggeno

oggenc in.wav -b 256 out.ogg cdparanoia -B lame -b 256 in.wav out.mp3
for i in \*.wav; do lame -b 256 \$i `basename \$i # Encode in Ogg Vorbis 256 kb/s # Encode in mp3 256 kb/s # Copy the tracks to wav files in current dir

.7 PRINTING

## 17.1 Print with Ipr

lpr -Php4500 #2 unixtoolbox.ps # Use pri
lpr -o Duplex=DuplexNoTumble ... # Print d
lpr -o PageSize=A4, Duplex=DuplexNoTumble ... lpq Lpq export PRINTER=hp4600 lpr unixtoolbox.ps -1 -Php4500 # Change the default printer
# Use printer hp4500 and print 2 copies
# Print duplex along the long side Check the queue on default printer Queue on printer hp4500 with verbo Print on default printer

                                                                                                                                                                                  port clean --all ghostscript
                                                                                                                                                                                                                                                                port -f uninstall installed
                                                                                                                                                                                                                                    port uninstall ghostscript
                                                                                                                              port variants ghostscript
                                                                                                                                                                                                              port upgrade ghostscript
                                                                                                     port install proctools
                                                    port deps apache2
                                                                             port search pgrep
port selfupdate
                           port installed
```

## 15.3 Library path

Due to complex dependencies and runtime linking, programs are difficult to copy to an other system or distribution. However for small programs with little dependencies, the missing libraries can be copied over. The runtime libraries (and the missing one) are checked with 1dd and managed with ldconfig.

```
OS X equivalent to 1dd
Add a path to the shared libraries directories
FreeBSD
                                                                                                       The variable set the link library path
List all needed runtime libraries
                                                       ldconfig -n /path/to/libs,
                                                                              ldconfig -m /path/to/libs
                              otool -L /usr/bin/rsync
# 1dd /usr/bin/rsync
                                                                                                       LD LIBRARY PATH
```

## **16 CONVERT MEDIA**

Sometimes one simply need to convert a video, audio file or document to another format

## 16.1 Text encoding

Text encoding can get totally wrong, specially when the language requires special characters like àäç. The command iconv can convert from one encoding to an other.

```
# List known coded character sets
# iconv -f <from encoding> -t <to encoding> <input file>
                                          iconv -f ISO8859-1 -t UTF-8 -o file.input > file_utf8
                                                                                     iconv -1
```

Without the -f option, iconv will use the local char-set, which is usually fine if the document displays well.

Convert filenames from one encoding to another (not file content). Works also if only some files are already utf8

## 16.2 Unix - DOS newlines

# convmv -r -f utf8 --nfd -t utf8 --nfc /dir/\* --notest

Convert DOS (CR/LF) to Unix (LF) newlines and back within a Unix shell. See also dos2unix and unix2dos if you have them

```
# DOS to UNIX
# DOS to UNIX
# UNIX to DOS
                                  awk '{sub(/\r\footnote{\text},"");print}' dosfile.txt > unixfile.txt awk '{sub(\\footnote{\text},"\r\");print}' unixfile.txt > dosfile.txt
   # sed 's/.$//' dosfile.txt > unixfile.txt
```

Check the "media" field on FreeBSD
                                                                   The first thing to try...
# ifconfig fxp0
                                                                      ping cb.vu
                                                                                                                                                                                  netstat -s
```

# Additional commands which are not always installed per default but easy to find:

```
toptraceroute -f 5 cb.vu # uses top instead of icmp to trace through firewalls
# Ping on ethernet layer
arping 192.168.16.254
```

### 4.2 Routing

### Print routing table

```
# Linux or use "ip route"
             Linux, BSD and UNIX Windows
               netstat -rn
                                route print
# route -n
```

## Add and delete a route

```
# route add 212.117.0.0/16 192.168.1.1
                                                  route add default 192.168.1.1
                        delete 212.117.0.0/16
                               route
```

## Add the route permanently in /etc/rc.conf

```
route_myroute="-net 212.117.0.0/16 192.168.1.1"
static routes="myroute"
```

```
# same as above with ip route
-net 192.168.20.0 netmask 255.255.255.0 gw 192.168.16.254
                                   ip route add 192.168.20.0/24 via 192.168.16.254 # sam
route add -net 192.168.20.0 netmask 255.255.255.0 dev eth0
route add default gw 192.168.51.254
route add
```

# ip route add default via 192.168.51.254 dev eth0
# route delete -net 192.168.20.0 netmask 255.255.255.0 # same as above with ip route

# route change default 192.168.50.254 1 route add default 192.168.51.254 1 route add -net 192.168.20.0 -netmask 255.255.255.0 192.168.16.254 # 1 = hops to the next gateway

Permanent entries are set in entry in /etc/defaultrouter.

# Route add 192.168.50.0 mask 255.255.255.0 192.168.51.253 # Route add 0.0.0.0 mask 0.0.0.0 192.168.51.254

Use add -p to make the route persistent.

# 4.3 Configure additional IP addresses

#### Linux

```
# ifconfig eth0 192.168.50.254 netmask 255.255.255.0
# ifconfig eth0:0 192.168.51.254 netmask 255.255.255.0
# ip addr add 192.168.50.254/24 dev eth0
# ip addr add 192.168.51.254/24 dev eth0 label eth0:1
                                                                                                                   # First IP
                                           Equivalent ip commands
                                                                                 Second IP
```

#### FreeBSD

```
Permanent entries in /etc/rc.conf
                                                                                                                                                                                  # ifconfig fxp0 inet 192.168.50.254/24 # First IP # ifconfig fxp0 alias 192.168.51.254 netmask 255.255.255.0 # Second IP
ifconfig_fxp0="inet 192.168.50.254 netmask 255.255.255.0"
                                                                                                                                          # ifconfig fxp0 -alias 192.168.51.254
                                                                                                                                              # Remove second IP alias
```

ifconfig\_fxp0\_alias0="192.168.51.254 netmask 255.255.25.0"

#### Solaris

Check the settings with ifconfig -a

## 4.4 Change MAC address

change the MAC address... Normally you have to bring the interface down before the change. Don't tell me why you want to

```
sudo ifconfig en0 ether 00:01:02:03:04:05
sudo ifconfig en0 lladdr 00:01:02:03:04:05
                                                    ifconfig eth0 hw ether 00:01:02:03:04:05 ifconfig fxp0 link 00:01:02:03:04:05 ifconfig hme0 ether 00:01:02:03:04:05
                                                                                                                                 ifconfig eth0 down
                                                                               # Linux
# FreeBSD
  # OS X Tiger, Snow Leopard LAN*
# OS X Leopard
                                                         Solaris
```

howto). \*Typical wireless interface is  $\mathtt{en1}$  and needs do disassociate from any network first (osxdaily

```
>> ~/.bash_profile
# airport -z
# airport -I
                                                                                                     # echo "alias airport='/System/Library/PrivateFrameworks/Apple80211.framework/Versions/Current/Resource
                                 or symlink to /usr/sbin
Disassociate from wireless networks
Get info from wireless network
```

Many tools exist for Windows. For example etherchange<sup>5</sup>. Or look for "Mac Makeup", "smac"

5.http://ntsecurity.nu/toolbox/etherchange

Install Software

export http\_proxy=http://proxy\_server:3128
export ftp\_proxy=http://proxy\_server:3128

## 15.1 List installed packages

	elong	es		, RPN
	ys t			ğ
	ö			sed)

## 15.2 Add/remove software

Front ends: yast2/yast for SuSE, redhat-config-packages for Red Hat.

#	#
mqr	rpm
Ð	占.
pkgname	pkgname.rpm
#	#
Remove package	install the package (RH, SuSE, RPM based)

# SuSE zypper (see doc and cheet sheet)<sup>27</sup>

<pre># zypper update vim</pre>	# zypper search vim	# zypper remove vim	<pre># zypper install vim</pre>	# zypper refresh
# Search packages with vim	# Search packages with vim	# Remove the package vim	# Install the package vim	# Refresh repositorie

#### Debian

# dpkg -S file	# dpkgremove emacs	# apt-get install emacs	# apt-get update
# find what package a file belongs to	# Remove the package emacs	# Install the package emacs	# First update the package lists

Gentoo uses emerge as the heart of its "Portage" package management system.

#	#	#	#
revdep-rebuild	emerge -C packagename	emerge -u packagename	emergesync
#	#	#	#
Repair depe	Remove the package	Install	First s
dep	the	Or	sync
enden	pac	odn	the
encies	kage	grade a	local
		Install or upgrade a package	First sync the local portage tree
			tree

#### Solaris

The <cdrom> path is usually /cdrom/cdrom0

#	#	#
pkgrm SUNWgtar	pkgadd -d SUNWgtar	<pre>pkgadd -d <cdrom>/Solaris_9/Produ</cdrom></pre>
		Ct
# Remove the package	# Add downloaded package (bunzip2 first)	SUNWGtar

### **FreeBSD**

#	#
D D D	pkg_add
delete	add -r :
pkg delete /var/db/pkg/rsvnc-xx	rsync
#	#
# Delete the	Fetch
the	and
H	Η.
Sync	nstall
rsvnc package	and install rsync.

Set where the packages are fetched from with the <code>PACKAGESITE</code> variable. For example:

```
# export PACKAGESITE=ftp://ftp.freebsd.org/pub/FreeBSD/ports/i386/packages/Latest/
# or ftp://ftp.freebsd.org/pub/FreeBSD/ports/i386/packages-6-stable/Latest/
```

### FreeBSD ports 28

The ports are updated with the program portsnap The port tree  $/{ t usr/ports}/$  is a collection of software ready to compile and install (see man ports).

# portsnap fetch update	# portsnap fetch extract
# Update the port tree	# Create the tree when running the first time

<sup>27.</sup>http://en.opensuse.org/SDB:Zypper\_usage

28.http://www.freebsd.org/handbook/ports.html

Be careful with xarg or exec as it might or might not honor quotings and can return wrong results when files or directories contain spaces. In doubt use "-print0 | xargs -0" instead of "| xargs". The option -print0 must be the last in the find command. See this nice mini tutorial for find<sup>26</sup>.

# I use above to add flac files to iTunes on OSX

## Duplicate directory tree:

# find . -type d -exec mkdir -p /tmp/new\_dest/{} \;

## 14.9 Miscellaneous

```
no error if existing, make parent dirs as needed
                                                                                                                                                                                                                                                                                     set env. variable varname to value (sh/ksh/bash)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Short way to copy the file with a new extension
                                                                                                                                                                                                                               Search path and standard directories for word
                                                                                                                                                                                                                                                          Set env. variable varname to value (csh/tcsh)
                                                                                                                                                                                                 Display a short info on the command or word
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Archive and hard link files instead of copy
                                                                                                                                                                                                                                                                                                                                                                                                                                                         Remove file whitch starts with a dash (-)
                                                                                                                                                                                                                                                                                                                                                                                                                            Remove directory and its content (force)
                             See how long a command takes to execute
                                                        Use time as stopwatch. Ctrl-c to stop

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        mv /dirl /dir2
which command
                                                                                                                                                                       date 10022155
                             time command
                                                                                                                                                                                                                               whereis java
                                                                                                                                                                                                 whatis grep
                                                        time cat
                                                                                                              cal -3
```

Check file hashes with openssl. This is a nice alternative to the commands md5sum or shalsum (FreeBSD uses md5 and shal) which are not always installed.

Generate an md5 checksum from file	enerate an shal checksum from file	rate a RIPEMD-160 checksum from file
# Gener	# Gener	# Gene
# openssl md5 file.tar.gz	# openssl shal file.tar.gz	# openssl rmd160 file.tar.gz

# 15 INSTALL SOFTWARE

Usually the package manager uses the proxy variable for http/ftp requests. In .bashrc:

26.http://www.hccfl.edu/pollock/Unix/FindCmd.htm

## 4.5 Ports in use

### Listening open ports:

```
List active connections to/from system (Linux)
                                                                                                                                        List listening ports from system (Linux)
                    Linux list all Internet connections
                                               Linux display list of open sockets
                                                                    FreeBSD application listing
                                                                                           grep LISTEN
                                                                                                                                                                 # Windows
netstat -an | grep LISTEN
                                                                                               --tcp
                                                                                             dpn--
                                                                                                                                        netstat -tupl
                                                                                             netstat -anp
                                                                                                                      netstat -tup
                                                                                                                                                                   netstat -ano
                                                                    sockstat -4
                                               socklist
```

### 4.6 Firewall

Check if a firewall is running (typical configuration only):

#### Linux

```
# iptables -L -n -v

# iptables firewall
# iptables -P INPUT ACCEPT
# iptables -P GVTPUT ACCEPT
# iptables -P OUTPUT ACCEPT
# iptables -Z
# iptables -Z
# iptables -F With all chains
# iptables -X
#
```

#### FreeBSD

## 4.7 IP Forward for routing

#### Linux

## Check and then enable IP forward with:

```
# cat /proc/sys/net/ipv4/ip_forward # Check IP forward 0=off, 1=on
# echo 1 > /proc/sys/net/ipv4/ip_forward
```

## or edit /etc/sysctl.conf with:

net.ipv4.ip\_forward = 1

#### FreeBSD

## Check and enable with:

```
# sysctl net.inet.ip.forwarding # Check IP forward 0=off, 1=on
# sysctl net.inet.ip.forwarding=1
# sysctl net.inet.ip.fastforwarding=1
# For dedicated router or firewall
Bermanent with entry in /etc/rc.conf:
# Set to YES if this host will be a gateway.
```

#### Solaris

# ndd -set /dev/ip ip\_forwarding 1 # Set IP forward 0=off, 1=on

# 4.8 NAT Network Address Translation

#### Ľ

```
# iptables -t nat -A POSTROUTING -o eth0 -j WASQUERADE # to activate NAT # iptables -t nat -A PREROUTING -p tcp -d 78.31.70.238 --dport 20022 -j DNAT \ --to 192.168.16.44:22
```

# iptables -L -t nat # iptables -t nat -A PREROUTING -p tcp -d 78.31.70.238 --dport 993:995 -j DNAT \
--to 192.168.16.254:993-995 # Port forward of range 993-995 # ip route flush cache # Check NAT status

Delete the port forward with -D instead of -A. The program netstat-nate is very useful to track connections (it uses /proc/net/ip\_conntrack or /proc/net/nf\_conntrack).

# netstat-nat -n # show all connections with IPs

```
natd_flags="-s -m -u -dynamic -f /etc/natd.conf"
                                 natd_interface="tun0"
                                                                             natd enable="YES"
                                                                                                                                                                                            Or edit /etc/rc.conf with:
                                                                                                                                                                                                                             # natd -s -m -u -dynamic -f /etc/natd.conf -n fxp0
                                                                                                                  firewall_type="open"
                                                                                                                                                       firewall_enable="YES"
                                    # Public interface or IP address to use.
                                                                             Enable natd (if firewall_enable == YES).
                                                                                                                  Firewall type (see /etc/rc.firewall)
                                                                                                                                                       Set to YES to enable firewall functionality
```

### Port forward with:

```
unregistered_only
# redirect_port top insideIP:2300-2399 3300-3399
redirect_port udp 192.168.51.103:7777 7777
                                                                                   use_sockets yes
                                                                                                               same_ports yes
                                                                                                                                        # cat /etc/natd.conf
                                # port range
```

#### 4.9 DNS

to which the host belongs is also stored in this file. A minimal configuration is: On Unix the DNS entries are valid for all interfaces and are stored in /etc/resolv.conf. The domain

```
Check the system domain name with:
                                          search sleepyowl.net intern.lab domain sleepyowl.net
                                                                                              nameserver 78.31.70.238
```

# Same as dnsdomainname

#### Windows

On Windows the DNS are configured per interface. To display the configured DNS and to flush the DNS cache use:

```
# ipconfig /?
# ipconfig /all
Display help
See all information including DNS
```

#### Flush DNS

Flush the OS DNS cache, some application using their own cache (e.g. Firefox) and unaffected <u>≦</u> be

```
ipconfig /flushdns
                      dscacheutil -flushcache
                                         lookupd -flushcache
                                                               /etc/init.d/nscd restart
                Restart nscd if used - Linux/BSD/Solaris
OS X Tiger
OS X Leopard and newer
```

### Forward queries

ns.second-ns.de can be used for testing. See from which server the client receives the answer Dig is you friend to test the DNS settings. For example the public DNS server 213.133.105.2 (simplified answer).

```
# dig sleepyowl.net
           78.31.70.238
```

## 14.7 screen

Screen (a must have) has two main functionalities:

- Run multiple terminal session within a single terminal.
  A started program is decoupled from the real terminal and can thus run in the background. The real terminal can be closed and reattached later.

## Short start example

start screen with:

Within the screen session we can start a long lasting program (like top)

Now detach with Ctrl-a Ctrl-d. Reattach the terminal with

In detail this means: If a session is running, then reattach. If necessary detach and logout remotely first. If it was not running create it and notify the user. Or:

Attach to a running screen in a multi display mode. The console is thus shared among multiple users. Very useful for team work/debug!

## Screen commands (within screen)

All screen commands start with Ctrl-a

- Ctrl-a? help and summary of functions
- Ctrl-a c create an new window (terminal)
- Ctrl-a Ctrl-n and Ctrl-a Ctrl-p to switch to the next or previous window in the list, number. ģ
- Ctrl-a Ctrl-N where N is a number from 0 to 9, to switch to the corresponding window
- Ctrl-a " to get a navigable list of running windows

Ctrl-a a to clear a missed Ctrl-a

- Ctrl-a Ctrl-d to disconnect and leave the session running in the background
- **Ctrl-a x** lock the screen terminal with a password
- Ctrl-a [ enter into scrollback mode, exit with esc.

Use echo "defscrollback 5000" > ~/.screenrc to increase buffer (default is 100)

- C-u Scrolls a half page up
- C-b Scroll a full page up
- C-d Scroll a half page down
- C-f Scroll a full page down
- Search forward
- ? Search backward

The screen session is terminated when the program within the running terminal is closed and you logout from the terminal.

### 14.8 Find

Some important options:

```
ST
                                                                                                   -iname
                                 -size n
                                                                                                                                                                 -x (on BSD) -xdev (on Linux)
                                                                                                                                  -exec cmd {} \;
  -cmin n
                                                              Display information about the file (like Is -la)
                                                                                                   Like -name but is case insensitive
File's status was last changed n minutes ago
                                    n is +-n (k M G T P)
                                                                                                                             Execute the command and replace {} with the full path
                                                                                                                                                                 Stay on the same file system (dev in fstab)
```

# find # find . -type f ! -perm -444 find . -name '\*.[ch]' | xargs grep -E 'expr' # Search 'expr' in this dir and below /home/user/ -cmin 10 -print . -type d ! -perm -111 # Files created or modified in the last 10 min. # Find files not readable by all # Find dirs not accessible by all

### 14.6 dd

The program  ${
m dd}$  (disk dump or destroy disk or see the meaning of  ${
m dd}$ ) is used to copy partitions and disks and for other copy tricks. Typical usage:

# View dd progress (FreeBSD, OSX) dd if=<source> of=<target> bs=<byte size> conv=<conversion>

important conv options:

do not truncate the output file, all zeros will be written as zeros. continue after read errors (e.g. bad blocks) pad every input block with Nulls to ibs-size noerror

The default byte size is 512 (one block). The MBR, where the partition table is located, is on the first block, the first 63 blocks of a disk are empty. Larger byte sizes are faster to copy but require also more memory.

## **Backup and restore**

```
# Copy disk to disk (same size)
                                                                                                                                                                                                                                                                                                                                                                                                \# This is necessary if the destination (ad2) is smaller. dd if=/vm/FreeBSD-8.2-RELEASE-amd64-memstick.img of=/dev/diskl bs=10240 conv=sync
                                                                                                                                                                                                         Restore the zip
                                                                                                                                                                                                                                               dd bs=1M if=/dev/ad4s3e | gzip | ssh eedcoba@fry 'dd of=ad4s3e.gz' # also remote
                                                                                                                                                 Zip the backup
                                     dd if=/dev/sda7 of=/home/root.img bs=4096 conv=notrunc.noerror # Backup /

dd bs=1M if=/dev/ad4s3e | gzip -c > ad4s3e.gz
                                                                                                                                                                                                                                                                                                                                                      # Skip MBR
                                                                                                                                                                                                                                                                                                       gunzip -dc ad4s3e.gz | ssh eedcoba@host 'dd of=/dev/ad0s3e bs=1M'
                                                                                                                                                                                                                                                                                                                                                      dd if=/dev/ad0 of=/dev/ad2 skip=1 seek=1 bs=4k conv=noerror
                                                                                                                                                                                                gunzip -dc ad4s3e.gz | dd of=/dev/ad0s3e bs=1M
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       # Copy FreeBSD image to USB memory stick
dd if=/dev/hda of=/dev/hdc bs=16065b
```

seems safe, set it with bs=1k. If a disk has bad sectors and the data should be recovered from The command ad will read every single block of the partition. In case of problems it is better to Accordingly it is important to set the block size equal or smaller than the disk block size. A 1k size With the option noexxox, dd will skip the bad sectors and write zeros instead, thus only the data a partition, create an image file with dd, mount the image and copy the content to a new disk. use the option convesync, noerror so dd will skip the bad block and write zeros at the destination. contained in the bad sectors will be lost.

# The above is useful to refresh a disk. It is perfectly safe, but must be unmounted. image # Refresh the magnetic state dd bs=1k if=/dev/hda1 conv=sync,noerror,notrunc | gzip | ssh \ # Send to remote # Mount the image (page 13) # Store into an # Check for bad blocks Copy on a new disk dd bs=1k if=/dev/hdal conv=sync,noerror,notrunc of=hdal.img # dd if=/dev/hda of=/dev/null bs=1m root@fry 'dd of=hdal.gz bs=1k' mount -o loop /hdal.img /mnt dd if=/dev/hda of=/dev/hda rsync -ax /mnt/ /newdisk/

#### Delete

```
(FreeBSD)
 # Delete full disk
# Delete full disk better
# View dd progress (Linux)
# View dd progress (FreeBSD
dd if=/dev/zero of=/dev/hdc
dd if=/dev/urandom of=/dev/hdc
                                         kill -USR1
                                                              kill - INFO
```

### **MBR** tricks

The MBR contains the boot loader and the partition table and is 512 bytes small. The first 446 are for the boot loader, the bytes 446 to 512 are for the partition table.

```
Backup the full MBR
 dd if=/dev/sda of=/mbr sda.bak bs=512 count=1
```

### – Network

The router 192.168.51.254 answered and the response is the A entry. Any entry can be queried and the DNS server can be selected with @:

```
dig (127.0.0.1 NS sun.com # To test the local server dig (204.97.212.10 NS MX heise.de # Query an external server dig AXFR (9nsl.xname.org cb.vu # Get the full zone (zone transfer)
```

```
connection
                            the mail MX entry
the NS record over a TCP
                              Get the mail MX
Get the NS recor
Get everything
The program host is also powerful
                              # host -t MX cb.vu
# host -t NS -T sun.com
                                                                        host -a sleepyowl.net
```

### Reverse queries

Find the name belonging to an IP address (in-addr.arpa.). This can be done with dig, host and nslookup:

```
nslookup 78.31.70.238
# dig -x 78.31.70.238
                     host 78.31.70.238
```

### /etc/hosts

Single hosts can be configured in the file /etc/hosts instead of running named locally to resolve the hostname queries. The format is simple, for example:

```
78.31.70.238 sleepyowl.net sleepyowl
```

The priority between hosts and a dns query, that is the name resolution order, can be configured in /etc/nsswitch.conf AND /etc/host.conf. The file also exists on Windows, it is usually in:

C:\WINDOWS\SYSTEM32\DRIVERS\ETC

### 4.10 DHCP

Some distributions (SuSE) use dhcpcd as client. The default interface is eth0.

```
# Trigger a renew (does not always work)
                          # release and shutdown
                        # dhcpcd -k eth0
  # dhcpcd -n eth0
```

The lease with the full information is stored in:

```
/var/lib/dhcpcd/dhcpcd-eth0.info
```

#### FreeBSD

FreeBSD (and Debian) uses dhclient. To configure an interface (for example bge0) run:

```
# dhclient bge0
```

```
/var/db/dhclient.leases.bge0
```

The lease with the full information is stored in:

/etc/dhclient.conf

```
default domain-name "sleepyowl.net";
supersede domain-name "sleepyowl.net";
                                                        prepend domain-name-servers 127.0.0.1;
# cat /etc/dhclient.conf
                               interface "rl0"
```

to prepend options or force different options:

### Windows

The dhcp lease can be renewed with ipconfig:

Yes it is a good idea to rename you adapter with simple names!

## 4.11 Traffic analysis

Bmon<sup>7</sup> is a small console bandwidth monitor and can display the flow on different interfaces.

## Sniff with tcpdump

```
# tcpdump -i eth0 -s 0 -A port 80 | grep GET
                                                                                                                                                                                                                                                                                                      tcpdump -n1 -i bge0 not port ssh and src \(192.168.16.121 or 192.168.16.54\) tcpdump -n -i eth1 net 192.168.16.121  # select tc/from a single IP tcpdump -n -i eth1 net 192.168.16.0/24  # select traffic tc/from a n
                                tcpdump -n -i eth0 icmp
                                                                       tcpdump -i eth0 -X port \(110 or 143\)
                                                                                                       tcpdump
                                                                                                                                        tcpdump
                                                                                                                                                                        tcpdump
                                                                                                                                                                                                        tcpdump -i rl0 -s 0 -w traffic.rl0
                                                                                                                                                                                                                                         tcpdump -i rl0 -w traffic.rl0
                                                                                                                                                                                                                                                                         tcpdump -1 > dump && tail -f dump
                                                                                                                                                                           -r traffic.rl0
                                                                                                       host google.com
                                                                                                                                           port 80

                                   Only catch pings
                                                                                                                                                                        Write traffic + payload in binary file Read from file (also for ethereal
                                                                                                                                                                                                                                         Write traffic headers in binary file
                                                                                                                                                                                                                                                                                                                select traffic to/from a network
                                                                Check if pop or imap is secure
                                                                                                                                                                                                                                                                                Buffered output
                                                                                                                                           The two classic commands
```

## Additional important options:

- Print each packets in clear text (without header)
- Print packets in hex and ASCII
- Make stdout line buffered
- $\frac{1}{2}$ Print all interfaces available

On Windows use windump from www.winpcap.org. Use windump -D to list the interfaces

### Scan with nmap

Nmap<sup>®</sup> is a port scanner with OS detection, it is usually installed on most distributions and is also available for Windows. If you don't scan your servers, hackers do it for you...

```
22/tcp
25/tcp
                                                                                                                                PORT
Uptime 33.120 days (since Fri Aug 31 11:41:04 2007)
                                                                                                                                                                                           # nmap
                    Running: FreeBSD 5.X
                                                               80/tcp
                                                                                                                                                     # nmap
                                                                                                                                                                         # nmap
                                                                                                                                                -sP 192.168.16.0/24 \# Find out which IP are used and by which host on 0/24 -sS -sV -0 cb.vu \# Do a stealth SYN scan with version and OS detection
                                                                                                                                                                                               cb.vu
                                                                                                        open
                                                                                   open
                                                                                                                                STATE SERVICE
                                                                 http
                                                                                   smtp
                                                                                                            ssh
                                                                                                                                                                                             # scans all reserved TCP ports on the host
                                                               Sendmail smtpd 8.13.6/8.13.6
Apache httpd 2.0.59 ((FreeBSD) DAV/2 PHP/4.
                                                                                                                                VERSION
                                                                                                        OpenSSH 3.8.1p1 FreeBSD-20060930 (protocol 2.0)
```

Other non standard but useful tools are  $\mathtt{hping}$  (www.hping.org) an IP packet assembler/analyzer and  $\mathtt{fping}$  (fping.sourceforge.net). fping can check multiple hosts in a round-robin fashion.

## 4.12 Traffic control (QoS)

Traffic control manages the queuing, policing, scheduling, and other traffic parameters for a network. The following examples are simple practical uses of the Linux and FreeBSD capabilities to better use the available bandwidth.

### Limit upload

queue with a fast device (e.g. ethernet) will dramatically decrease the interactivity. It is therefore useful to limit the device upload rate to match the physical capacity of the modem, this should greatly improve the interactivity. Set to about 90% of the modem maximal (a.t.)

20

## Useful Commands

### 14.3 mail

an email simply type "mail user@domain". The first line is the subject, then the mail content. Terminate and send the email with a single dot (.) in a new line. Example: The mail command is a basic application to read and send email, it is usually installed. To send

```
This is also working with a pipe
                                                                                                                                                              "For a moment, nothing happened. Then, after a second or so, nothing continued to happen."
                                                                                                                                                                                                                                   Subject: Your text is full of typos
                                                                                                                                                                                                                                                                           # mail c@cb.vu
```

```
# echo "This is the mail body" | mail c@cb.vu
```

This is also a simple way to test the mail server

#### 14.4 tar

else. Some typical commands are: Do not use absolute path when creating an archive, you probably want to unpack it somewhere The command an (tape archive) creates and extracts archives of file and directories. The archive tar is uncompressed, a compressed archive has the extension .tgz or .tar.gz (zip) or .tbz (bzip2).

```
# tar -czf home.tgz home/
# tar -cjf home.tbz home/
                                                      tar -cf home.tar home/
                                                                                 cd /
  # same with bzip2 compression
                                                 # archive the whole /home directory (c for create)
                        same with zip compression
```

Only include one (or two) directories from a tree, but keep the relative structure. For example archive /usr/local/etc and /usr/local/www and the first directory in the archive should be local/.

```
# cd /usr; tar -xzf local.tgz
                                                 tar -C /usr -czf local.tgz
                        tar -C /usr -xzf local.tgz
                                                     local/etc local/www
# To untar the local dir into /usr
# Is the same as above
```

#### Extract

```
tar
                                                                                                                                                          tar -tzf home.tgz
     tar -xOf home.tbz home/colin/file.txt
                                  tar
                                                                                                                            tar -xzf home.tgz
                                                             --strip-components 1 -zxvf gallery2.tgz -C gallery/
                               -xjf home.tbz
                                  home/colin/file.txt
                                                                                                                                                                                    # look inside the archive without extracting (list)
                                                                                            remove leading path gallery2 and extract into gallery
                                                                                                                            same with zip compression (-xjf for bzip2 compression)
                                                                                                                                                          extract the archive here (x for extract)
# Print file to stdout (no extraction)
                             # Restore a single file
```

### More advanced

```
# tar c dir/ | gzip | ssh user@remote 'dd of=dir.tgz' # arch dir/ and store remotely.
                       tar cvf - `find . -print` > backup.tar
tar -czf home.tgz --exclude '*.o' --exclude 'tmp/' home/
                                                     # Copy directories
                                                                               # arch the current directory.
                          # Remote copy
```

## 14.5 zip/unzip

Zip files can be easier to share with Windows

```
# unzip -1 fileName.zip
                                                                                                                                # zip -r fileName.zip /path/to/dir
# unzip -c fileName.zip fileinside.txt
# unzip fileName.zip fileinside.txt
                                                                                                 # unzip fileName.zip
                                                                                                                                   # zip dir into file fileName.zip
                                 print one file to stdout (no extraction)
                                                                list files inside archive
                                                                                                 uncompress zip file
```

<sup>7.</sup>http://people.suug.ch/~tgr/bmon, 8.http://insecure.org/nmap/

Move (rename) files Delete files svn delete some old file svn move foo.c bar.c

# 14 USEFUL COMMANDS

less (p40) | vi (p40) | mail (p41) | tar (p41) | zip (p41) | dd (p42) | screen (p43) | find (p43) Miscellaneous (p44)

### 14.1 less

The less command displays a text document on the console. It is present on most installation.

# less unixtoolbox.xhtml

Some important commands are ( $^{\wedge}N$  stands for [control]-[N]):

good help on display

Forward one window (or N lines). f ^F ^V SPACE

Backward one window (or N lines). Forward forever; like "tail -f". b ^B ESC-v

Search forward for (N-th) matching line. /pattern

Search backward for (N-th) matching line. Repeat previous search (for N-th occurrence) ?pattern

Repeat previous search in reverse direction. Z

σ

#### 14.2 vi

Vi is present on ANY Linux/Unix installation (not gentoo?) and it is therefore useful to know some basic commands. There are two modes: command mode and insertion mode. The commands mode is accessed with **[ESC]**, the insertion mode with **i**. Use: help if you are lost.

The editors nano and pico are usually available too and are easier (IMHO) to use.

Quit

save the file to newfilename save and quit quit without saving :w newfilename :wd or :x

### Search and move

Search for previous instance of string Search for next instance of string Move to the n th line of the file Move to the first line of the file Search forward for string Search back for string Move a paragraph forward Move a paragraph back /string String

Search and replace every occurrence Move to the last line of the file :%s/OLD/NEW/g U

## Delete copy paste text

Cut current line (word) Cut to the end of the line Delete (cut) character (wp) pp ۵ ×

Copy line (word) after cursor yy (yw) P

Undo last modification Paste after cursor

Undo all changes to current line

40

Network

#### Linux

## For a 512 Kbit upload modem.

```
tc -s gdisc ls dev eth0 # Status
tc gdisc del dev eth0 root # Delete the queue
tc gdisc change dev eth0 root tbf rate 220kbit latency 50ms burst 1540
# tc qdisc add dev eth0 root tbf rate 480kbit latency 50ms burst 1540
```

#### FreeBSD

-reeBSD uses the dummynet traffic shaper which is configured with ipfw. Pipes are used to set limits the bandwidth in units of [K|M]{bit/s|Byte/s}, 0 means unlimited bandwidth. Using the same pipe number will reconfigure it. For example limit the upload bandwidth to 500 Kbit.

```
# create a pipe with limited bandwidth
# divert the full upload into the pipe
  # load the module if necessary
                                                              # ipfw add pipe 1 ip from me to any
                             ipfw pipe 1 config bw 500Kbit/s
# kldload dummynet
```

### Quality of service

www.howtoforge.com. Suppose VoIP uses udp on ports 10000:11024 and device eth0 (could also be ppp0 or so). The following commands define the QoS to three queues and force the VoIP traffic to queue 1 with QoS ox1e (all bits set). The default traffic flows into queue 3 and QoS Minimize-Priority queuing with to to optimize VoIP. See the full example on voip-info.org Delay flows into queue 2.

```
# tc gdisc add dev eth0 root handle 1: prio priomap 2 2 2 2 2 2 1 1 1 1 1 1 1 0
# tc gdisc add dev eth0 parent 1:1 handle 10: sfq
# tc gdisc add dev eth0 parent 1:2 handle 20: sfq
# tc gdisc add dev eth0 parent 1:3 handle 20: sfq
# tc fditer add dev eth0 parent 1:3 handle 30: sfq
# tc filter add dev eth0 protocol ip parent 1: prio 1 u32 \
                                                                                                                                                                                                                                                                  # use server port range
                                                                                                                                                                                                                                                                                                                       or/and use server IP
                                                                                                                                                                                                                                                             match ip dport 10000 0x3C00 flowid 1:1
                                                                                                                                                                                                                                                                                                                  match ip dst 123.23.0.1 flowid 1:1
```

## Status and remove with

```
# delete all QoS
# queue status
                     tc gdisc del dev eth0 root
# tc -s qdisc ls dev eth0
```

## Calculate port range and mask

*ending* of the port range, deduce the range and convert to HEX. This is your mask. Example for The tc filter defines the port range with port and mask which you have to calculate. Find the  $2^{\wedge} N$ 10000 -> 11024, the range is 1024.

```
\# ending is 2^{14} = 16384
# 2^13 (8192) < 10000 < 2^14 (16384)
                                # echo "obase=16; (2~14)-1024" | bc
```

#### FreeBSD

The max link bandwidth is 500Kbit/s and we define 3 queues with priority 100:10:1 for VoIP:ssh:all

```
ipfw add 10 queue 1 proto udp dst-port 10000-11024 ipfw add 11 queue 1 proto udp dst-ip123.23.0.1\ \# or/and use server IP
                                                                                                                                                                                                                                                            # all the rest
                                     ipfw queue 1 config pipe 1 weight 100 ipfw queue 2 config pipe 1 weight 10
                                                                                                      ipfw queue 3 config pipe 1 weight 1
                                                                                                                                                                                                                                                            ipfw add 30 queue 3 from me to any
                                                                                                                                                                                                                          ipfw add 20 queue 2 dsp-port ssh
# ipfw pipe 1 config bw 500Kbit/s
```

## Status and remove with

```
# pipe status
# deletes all rules but default
 rules status
              ipfw pipe list
ipfw flush
# ipfw list
```

## 4.13 NIS Debugging

Some commands which should work on a well configured NIS client:

```
# rpcinfo -p servername
                   ypcat group
cd /var/yp && make
    # Report RPC services of the server
                           # Rebuild the yp database
                                                   should display the group from the NIS server
```

### Is ypbind running?

```
Map passwd.byname has order number 1190635041. Mon Sep 24 13:57:21 2007 The master server is servername.domain.net.
                                                                                                                                                            # ps auxww | grep ypbind
                                                               # yppoll passwd.byname
                                                                                             /usr/sbin/ypbind
                                                                                                                              /usr/sbin/ypbind -s -m -S
                                                                                                                              servername1, servername2
```

domain domain.net broadcast

### # cat /etc/yp.conf

### 4.14 Netcat

example g-loaded.eu[...]10 and here11 Netcat<sup>®</sup> (nc) is better known as the "network Swiss Army Knife", it can manipulate, create or read/write TCP/IP connections. Here some useful examples, there are many more on the net, for

You might need to use the command  $\mathtt{netcat}$  instead of  $\mathtt{nc}.$  Also see the similar command socat.

Copy a large folder over a raw tcp connection. The transfer is very quick (no protocol overhead) and you don't need to mess up with NFS or SMB or FTP or so, simply make the file available on the server, and get it from the client. Here 192.168.1.1 is the server IP address.

```
server# tar -cf - C VIDEO_TS . | nc -l -p 4444 client# nc 192.168.1.1 4444 | tar xpf - C VIDEO_TS server# cat largefile | nc -l 5678 client# nc 192.168.1.1 5678 > largefile server# dd iff/dey/da0 | nc -l 4444
client# nc 192.168.1.1 4444 | dd of=/dev/da0 client# nc 192.168.1.1 4444 | dd of=da0.img
Pull partition to clone Pull partition to file
                                                              Server partition image
                                                                                                                         Server a single file
                                                                                                                                                                                     Serve tar folder on port 4444
                                                                                               Pull the single file
                                                                                                                                                          Pull the file on port 4444
```

Specially here, you must know what you are doing

### Remote shell

Option -e only on the Windows version? Or use nc 1.10.

```
# nc -lp 4444 -e /bin/bash
# nc -lp 4444 -e cmd.exe
                            # Provide a remote shell (server backdoor)
     # remote shell for Windows
```

## Emergency web server

Serve a single file on port 80 in a loop.

```
# while true; do nc -1 -p 80 < unixtoolbox.xhtml; done
```

Alice and Bob can chat over a simple TCP socket. The text is transferred with the enter key.

```
alice# nc -lp 4444
bob # nc 192.168.1.1 4444
```

## Remote access with http (apache)

the apache authentication, not the local accounts. This is a typical but small apache configuration: Remote access over http (https) is the only good solution for a larger user group. This method uses

```
<Location /svn>
                                                                                                                                                                                                                                                                                  LoadModule authz_svn_module
                                                                                                                                                                                                                                                                                                                 LoadModule dav_svn_module
                                                                                                                                                                                                                                                                                                                                                LoadModule dav_module
                                                  AuthName "Subversion repository" AuthzSVNAccessFile /etc/apache2/svn.acl
                                                                                                                 AuthType Basic
                                                                                                                                                SVNParentPath /home/svn
Require valid-user
                            AuthUserFile /etc/apache2/svn-passwd
                                                                                                                                                                            # any "/svn/foo" URL will map to a repository /home/svn/foo
                                                                                                                                                                                                                                                                                  modules/mod_authz_svn.so
                                                                                                                                                                                                                                                                                                                 modules/mod_dav_svn.so
                                                                                                                                                                                                                                                                                                                                                   modules/mod_dav.so
                                                                                                                                                                                                                                                                                     # Only for access control
```

The apache server needs full access to the repository:

```
# chown -R www:www /home/svn
```

## Create a user with htpasswd2

# htpasswd -c /etc/svn-passwd userl # -c creates the file

## Access control svn.acl example

```
@project1-developers = rw
                                                      project1-developers = joe,
# Give write access to the
                                                                                                                                                                                               # Default it read access. "* =" would be default no access
                            [project1:]
                                                      jack, jane
developers
```

# 13.2 SVN commands and usage

See also the Subversion Quick Reference Card<sup>24</sup>. Tortoise SVN<sup>25</sup> is a nice Windows interface.

command. Import is also used to add a directory with its content to an existing project A new project, that is a directory with some files, is imported into the repository with the import

```
import /projectl/newdir http://host.url/svn/projectl/trunk/src -m 'add newdir'
                                                   Add a new directory (with content) into the src dir on project1
                                                                                                            # Get help for any command
```

## Typical SVN commands

```
# svn co http://host.url/svn/project1/trunk
                                                                                                                                                                                       svn copy -m "Tag rcl rel." http://host.url/svn/project1/trunk \
                                                                                                                                                                                                                            svn mkdir http://host.url/svn/project1/tags/
                                                                                                                                                                                                                                                                   # Tags and branches are created by copying
                                                                add src/file.h src/file.cpp
ls http://host.url/svn/project1/tags/
                                    commit -m 'Added new class file'
                                                                                                                                                   http://host.url/svn/project1/tags/1.0rc1
                                                                                                                                                                                                                            # Create the tags directory
                                                                                                                                                                                                                                                                                                           # Checkout the most recent version
                                    Commit the changes with a message
                                                                                                            Check files status into working dir
```

24.http://www.cs.put.poznan.pl/csobaniec/Papers/svn-refcard.pdf 25.http://tortoisesvn.tigris.org

```
Commit all changes done with a message
  option)
Reset any sticky tag (or date,
                  Add a new file
Add a new binary file
Commit the two files only
# cvs update -A
# cvs add newfile
# cvs add -kb newfile
# cvs commit file1 file2
# cvs commit -m "message"
```

### Create a patch

It is best to create and apply a patch from the working development directory related to the project, or from within the source directory

```
diff -Naur olddir newdir > patchfile # Create a patch from a directory or a file
diff -Naur oldfile newfile > patchfile
cd /devel/project
```

### Apply a patch

Sometimes it is necessary to strip a directory level from the patch, depending how it was created In case of difficulties, simply look at the first lines of the patch and try -p0, -p1 or -p2.

```
# strip off the 1st level from the path
                          # Test the path without applying
                          patch --dry-run -p0 < patchfile
                                                     patch -p0 < patchfile
patch -p1 < patchfile
cd /devel/project
```

#### SVR 13

Server setup (p38) | SVN+SSH (p38) | SVN over http (p39) | SVN usage (p39)

Subversion (SVN)<sup>22</sup> is a version control system designed to be the successor of CVS (Concurrent Versions System). The concept is similar to CVS, but many shortcomings where improved. See also the SVN book23.

## 13.1 Server setup

The initiation of the repository is fairly simple (here for example /home/svn/ must exist):

```
Now the access to the repository is made possible with:
# svnadmin create --fs-type fsfs /home/svn/project1
```

- file:// Direct file system access with the svn client with. This requires local permissions on the file system.
  - svn:// or svn+ssh:// Remote access with the svnserve server (also over SSH). This requires local permissions on the file system (default port: 2690/tcp)
- http:// Remote access with webdav using apache. No local users are necessary for this method.

Using the local file system, it is now possible to import and then check out an existing project. Unlike with CVS it is not necessary to cd into the project directory, simply give the full path:

```
# svn import /project1/ file:///home/svn/project1/trunk -m 'Initial import'
                                                     # svn checkout file:///home/svn/project1
```

The new directory "trunk" is only a convention, this is not required

## Remote access with ssh

No special setup is required to access the repository via ssh, simply replace  ${ t file://}$  with  ${ t svn+ssh}/$ hostname. For example:

```
# svn checkout svn+ssh://hostname/home/svn/project1
```

As with the local file access, every user needs an ssh access to the server (with a local account) and also read/write access. This method might be suitable for a small group. All users could belong to a subversion group which owns the repository, for example:

38

SSH SCP

Public key (p23) | Fingerprint (p23) | SCP (p24) | Tunneling (p24)

See other tricks 25 ssh cmd12

## 5.1 Public key authentication

public key to the authorized\_keys2 file on the remote host. For this example let's **connect host-client to host-server**, the key is generated on the client. With cygwin you might have to create Connect to a host without password using public key authentication. The idea is to append your your home directoy and the .ssh directory with # mkdir -p /home/USER/.ssh

- /\rss\/~ Use ssh-keygen to generate a key pair. ~/.ssh/id dsa is the private key, id dsa.pub is the public key.
- Copy only the public key to the server and append it to the file ~/.ssh/authorized keys2 on your home on the server.

```
cat \sim/.ssh/id dsa.pub | ssh you@host-server "cat - >> \sim/.ssh/authorized keys2"
ssh-keygen -t dsa -N''
```

# Using the Windows client from ssh.com

ftp.ssh.com/pub/ssh/. Keys generated by the ssh.com client need to be converted for the OpenSSH be downloaded the main ftp The non commercial version of the ssh.com client can server. This can be done with the ssh-keygen command.

- Create a key pair with the ssh.com client: Settings User Authentication Generate New....
  - I use Key type DSA; key length 2048.
- Settings\%USERNAME%\Application Copy the public key generated by the ssh.com client to the server into the ~/.ssh folder. and C:\Documents Data\SSH\UserKeys. are keys
  - Use the ssh-keygen command on the server to convert the key:

```
ssh-keygen -i -f keyfilename.pub >> authorized_keys2
# cd ~/.ssh
```

Notice: We used a DSA key, RSA is also possible. The key is not protected by a password.

## Using putty for Windows

Putty<sup>13</sup> is a simple and free ssh client for Windows.

- Create a key pair with the puTTYgen program.
- C:\Documents into (for example keys public and private Settings\%USERNAME%\.ssh)

and

Copy the public key to the server into the ~/.ssh folder:

```
# scp .ssh/puttykey.pub root@192.168.51.254:.ssh/
```

Use the ssh-keygen command on the server to convert the key for OpenSSH

```
# ssh-keygen -i -f puttykey.pub >> authorized_keys2
# cd ~/.ssh
```

Point the private key location in the putty settings: Connection - SSH - Auth

## 5.2 Check fingerprint

At the first login, ssh will ask if the unknown host with the fingerprint has to be stored in the known fingerprint which is then compared on the first login. Use ssh-keygen -1 to get the fingerprint (on hosts. To avoid a man-in-the-middle attack the administrator of the server can send you the server the server):

```
# ssh-keygen -1 -f /etc/ssh/ssh_host_rsa_key.pub # For RSA key
2048 61:33:be:9b:ae:6c:36:31:fd:83:98:b7:99:2d:9f:cd /etc/ssh/ssh_host_rsa_key.pub
```

<sup>22.</sup>http://subversion.tigris.org/ 23.http://svnbook.red-bean.com/en/1.4/

<sup>12.</sup>http://blog.urfx.com/25-ssh-commands-tricks/ 13.http://www.chiark.greenend.org.uk/~sgtatham/putty/download.html

# ssh-keygen -1 -f /etc/ssh/ssh\_host\_dsa\_key.pub # For DSA key (default) 2048 14:4a:aa:d9:73:25:46:6d:0a:48:35:c7:f4:16:d4:ee /etc/ssh/ssh\_host\_dsa\_key.pub

Now the client connecting to this server can verify that he is connecting to the right server:

DSA Are you sure you want to continue connecting (yes/no)? yes The authenticity of host 'linda (192.168.16.54)' can't be established. key fingerprint is 14:4a:aa:d9:73:25:46:6d:0a:48:35:c7:f4:16:d4:ee

## Secure file transfer

## Some simple commands

```
# scp -r joe@host-two:/www /www/tmp
                                   scp joe@host-two:/www/*.html /www/tmp
                                                                       scp file.txt host-two:/tmp
```

In Konqueror or Midnight Commander it is possible to access a remote file system with the address

See fuse sshfs14. **fish://user@gate**. However the implementation is very slow.
Furthermore it is possible to mount a remote folder with **sshfs** a file system client based on SCP.

ssh\_exchange\_identification: Connection closed by remote host

# With this error try the following on the server:

```
echo 'SSHD: ALL' >> /etc/hosts.allow
/etc/init.d/sshd restart
```

### 5.4 Tunneling

general nomenclature for forward and reverse is (see also ssh and NAT example): SSH tunneling allows to forward or reverse forward a port over the SSH connection, thus securing the traffic and accessing ports which would otherwise be blocked. This only works with TCP. The

```
# ssh -R destport:desthost:localport user@gate # forwards your localport to destination
# desthost:localport as seen from the client initiating the tunnel
                                                                                                                                                                                                   # ssh -I localport:desthost:destport user@gate # desthost as seen from the gate
# To force X forwarding
```

is the destination host as seen by the gate, so if the connection is to the gate, then desthost is localhost. More than one port forward is possible. This will connect to gate and forward the local port to the host desthost:destport. Note desthost

## Direct forward on the gate

80 so we don't need to be root. Once the ssh session is open, both services are accessible on the Let say we want to access the CVS (port 2401) and http (port 80) which are running on the gate. This is the simplest example, desthost is thus localhost, and we use the port 8080 locally instead of

# ssh -L 2401:localhost:2401 -L 8080:localhost:80 user@gate

# Netbios and remote desktop forward to a second server

smb share and also remote desktop to the server. Let say a Windows smb server is behind the gate and is not running ssh. We need access to the

# ssh -L 139:smbserver:139 -L 3388:smbserver:3389 user@gate

because the local share is listening on port 139. The smb share can now be accessed with  $\127.0.0.1\$  but only if the local share is disabled

new IP address for the tunnel, the smb share will be connected over this address. Furthermore the 10.1.1.1*local RDP is already listening on 33*89, so we choose 3388. For this example let's use a virtual IP of It is possible to keep the local share enabled, for this we need to create a new virtual device with a

With putty use Source port=10.1.1.1:139. It is possible to create multiple loop devices and tunnel. On Windows 2000, only putty worked for me. On Windows Vista also forward the

14.http://fuse.sourceforge.net/sshfs.html

## CVSROOT variable

a csh, tcsh shell, or with export CVSROOT=string on a sh, bash shell transport protocol must be specified. Set the CVSROOT variable with setenv CVSROOT string on. For local use, it can be just set to the directory of the repository. For use over the network, the This is an environment variable used to specify the location of the repository we're doing operations on.

```
For example:
                                                                                                                                                           # setenv CVSROOT :pserver:<username>@<host>:/cvsdirectory
  setenv CVSROOT :pserver:user@cvsserver.254:/usr/local/cvs
                                                                                                         setenv CVSROOT /usr/local/cvs
                             setenv CVS_RSH
                                                   setenv CVSROOT
                                                                                 setenv CVSROOT
                                ssh
                                                      :ext:user@cvsserver:/usr/local/cvs
                                                                              :local:/usr/local/cvs
# network with pserver
                                for the ext access
                                                   Direct access with SSH
                                                                                 Same as above
                                                                                                         Used locally only
```

root directory When the login succeeded one can import a new project into the repository: **cd into** your project

```
cvs import <module name> <vendor tag> <initial tag>
cvs -d :pserver:colin@192.168.50.254:/usr/local/cvs import MyProject MyCompany START
```

Where MyProject is the name of the new project in the repository (used later to checkout). Cvs will import the current directory content into the new project.

```
# cvs checkout MyProject
                                                                                                                                                              # cvs -d :pserver:colin@192.168.50.254:/usr/local/cvs checkout MyProject
                                                    setenv CVSROOT :pserver:colin@192.168.50.254:/usr/local/cvs
```

## 12.3 SSH tunneling for CVS

on shell 1: the cvs connection. On the second shell we use the cvs normally as if it where running locally. We need 2 shells for this. On the first shell we connect to the cvs server with ssh and port-forward

```
# ssh -L2401:localhost:2401 colin@cvs_server # ssh -L2401:cvs_server:2401 colin@gateway
   # Connect directly to the CVS server. Or:
# Use a gateway to reach the CVS
```

#### on shell 2:

```
# cvs checkout MyProject/src
                                   CVS password:
                                                                                                             # cvs login
                                                                                                                                             # setenv CVSROOT :pserver:colin@localhost:/usr/local/cvs
                                                                      Logging in to :pserver:colin@localhost:2401/usr/local/cvs
```

# 12.4 CVS commands and usage

directory name on the CVS (the module) will be called "myapp". to be imported. Say the directory /devel/ contains all files and subdirectories to be imported. The The import command is used to add a whole directory, it must be run from within the directory

```
# cvs import myapp Company R1_0
                                              cvs import [options] directory-name vendor-tag release-tag cd /devel \, # Must be inside the \ensuremath{\text{pro}}
# Must be inside the project to import it
# Release tag can be anything in one word
```

After a while a new directory "/devel/tools/" was added and it has to be imported too

```
cvs import myapp/tools Company R1_0
                              cd /devel/tools
```

## Checkout update add commit

```
# cvs co -r R1_1 myapp
# cvs -q -d update -P
                                                   # cvs co myapp/tools
# A typical CVS
                         Checkout myapp at release R1_1 (is sticky)
                                                     Will only checkout the directory tools
```

files directly into the main cvs, but rather checkout the file, modify it and check it in. We did this Add a **readers** file if you want to differentiate read and write permissions  $\mathit{Note}$ : Do not (ever) edit with the file writers to define the write access.

There are three popular ways to access the CVS at this point. The first two don't need any further configuration. See the examples on CVSROOT below for how to use them:

- Direct local access to the file system. The user(s) need sufficient file permission to access the CS directly and there is no further authentication in addition to the OS login. However this is only useful if the repository is local.
  - write permissions on the CVS server can access the CVS directly with ext over ssh without any additional tunnel. There is no server process running on the CVS for this to work. The Remote access with ssh with the ext protocol. Any use with an ssh shell account and read/ ssh login does the authentication.
- password Remote access with pserver (default port: 2401/tcp). This is the preferred use for larger user base as the users are authenticated by the CVS pserver with a dedicated password database, there is therefore no need for local users accounts. This setup is explained below.

## Network setup with inetd

The CVS can be run locally only if a network access is not needed. For a remote access, the daemon inetd can start the pserver with the following line in /etc/inetd.conf (/etc/xinetd.d/cvs on SuSE):

```
cvs /
stream tcp nowait cvs /usr/bin/cvs
                           --allow-root=/usr/local/cvs pserver
```

is a good idea to block the cvs port from the Internet with the firewall and use an ssh tunnel to access the repository remotely.

## Separate authentication

is possible to have cvs users which are not part of the OS (no local users). This is actually probably wanted too from the security point of view. Simply add a file named **passwd** (in the CVSROOT directory) containing the users login and password in the crypt format. This is can be done with the apache htpasswd tool.

Note: This passwd file is the only file which has to be edited directly in the CVSROOT directory. Also it won't be checked out. More info with htpasswd --help

```
# htpasswd -cb passwd user1 password1 # -c creates the file
                                                    # htpasswd -b passwd user2 password2
```

Now add  $\cos s$  at the end of each line to tell the cvs server to change the user to cvs (or whatever your cvs server is running under). It looks like this:

user1:xsFjhU22u8Fuo:cvs user2:vnefJOsnnvToM:cvs # cat passwd

### **12.2 Test it**

Test the login as normal user (for example here me)

# cvs -d :pserver:colin@192.168.50.254:/usr/local/cvs login Logging in to :pserver:colin@192.168.50.254:2401/usr/local/cvs CVS password:

port 445 in addition to the port 139. Also on Vista the patch KB942624 prevents the port 445 to be forwarded, so I had to uninstall this path in Vista.

- 2 With the ssh.com client, disable "Allow local connections only". Since ssh.com will bind all addresses, only a single share can be connected.
  - # System->Control Panel->Add Hardware # Yes, Hardware is already connected # Add a Now create the loopback interface with IP 10.1.1.1: new hardware device (at bottom).
- # Install the hardware that I manually select # Network adapters # Microsoft , Microsoft Loopback Adapter.
- Configure the IP address of the fake device to 10.1.1.1 mask 255.255.25.0, no gateway.
  - advanced->WINS, Enable LMHosts Lookup; Disable NetBIOS over TCP/IP.
- # Enable Client for Microsoft Networks. # Disable File and Printer Sharing for Microsoft Networks.

I HAD to reboot for this to work. Now connect to the smb share with \\10.1.1.1 and remote desktop to 10.1.1.1:3388.

If it is not working:

- Are the ports forwarded: netstat -an? Look at 0.0.0.0:139 or 10.1.1.139
  - Does telnet 10.1.1.1 139 connect?
- You need the checkbox "Local ports accept connections from other hosts"
- Is "File and Printer Sharing for Microsoft Networks" disabled on the loopback interface?

## Connect two clients behind NAT

(the destination), both can login to the gate with ssh and are running Linux with sshd. You don't Suppose two clients are behind a NAT gateway and client cliadmin has to connect to client cliuser need root access anywhere as long as the ports on gate are above 1024. We use 2022 on gate. Also since the gate is used locally, the option GatewayPorts is not necessary.

On client cliuser (from destination to gate):

# forwards client 22 to gate: 2022 On client cliadmin (from host to gate): # ssh -R 2022:localhost:22 user@gate

# forwards client 3022 to gate:2022 # ssh -L 3022:localhost:2022 admin@gate

Now the admin can connect directly to the client cliuser with:

# local:3022 -> gate:2022 -> client:22 # ssh -p 3022 admin@localhost

## Connect to VNC behind NAT

Suppose a Windows client with VNC listening on port 5900 has to be accessed from behind NAT. On client cliwin to gate:

# ssh -R 15900:localhost:5900 user@date

On client cliadmin (from host to gate):

# ssh -L 5900:localhost:15900 admin@gate

Now the admin can connect directly to the client VNC with:

# vncconnect -display :0 localhost

## Dig a multi-hop ssh tunnel

example because of routing issues). Sometimes it is still necessary to get a direct client - server connection, for example to copy files with scp, or forward other ports like smb or vnc. One way to do this is to chain tunnels together to forward a port to the server along the hops. This "carrier" Suppose you can not reach a server directly with ssh, but only via multiple intermediate hosts (for

port only reaches its final destination on the last connection to the server. Suppose we want to forward the ssh port from a client to a server over two hops. Once the tunnel is build, it is possible to connect to the server directly from the client (and also add an other port orward)

## Create tunnel in one shell

client -> host1 -> host2 -> server and dig tunnel 5678

host\_1># ssh -L5678:localhost:5678 host2 host\_2># ssh -L5678:localhost:22 server client># ssh -L5678:localhost:5678 host1 5678 is an arbitrary port for the tunnel chain 5678 from host1 to host2 end the tunnel on port 22 on the server

## Use tunnel with an other shell

client -> server using tunnel 5678

# scp -P 5678 myfile localhost:/tmp/ # or copy a file directly using the tunnel # rsync -e 'ssh -p 5678' myfile localhost:/tmp/ # or rsync a file directly to the server ssh -p 5678 localhost scp -P 5678 myfile localhost:/tmp/ # connect directly from client to

## Autoconnect and keep alive script

I use variations of the following script to keep a machine reacheable over a reverse ssh tunnel. connection is automatically rebuilt if closed. You can add multiple -1 or -1 tunnels on one line. The

1 \* \* \* \* colin /home/colin/port\_forward.sh pgrep -f -x "\$COMMAND" > /dev/null 2>&1 || \$COMMAND COMMAND="ssh -N -f -g -R 3022:localhost:22 colin@cb.vu" # crontab entry (here hourly)

## 6 VPN WITH SSH

pre shared keys. The drawback is that the encapsulation is done over TCP which might result in any case, the following options are needed in the sshd\_conf file: technique is very useful for a quick IP based VPN setup. There is no limitation as with the single poor performance on a slow link. Also the tunnel is relying on a single (fragile) TCP connection. This other TLS based VPN solutions like OpenVPN. One advantage with SSH is that there is no need to As of version 4.3, OpenSSH can use the tun/tap device to encrypt a tunnel. This is very similar TCP port forward, all layer 3/4 protocols like ICMP, TCP/UDP, etc. are forwarded over the VPN. In install and configure additional software. Additionally the tunnel uses the SSH authentication like

PermitTunnel yes PermitRootLogin yes

## 6.1 Single P2P connection

started from helient to herever and is done as root. The tunnel end points are 10.0.1.1 (server) and Here we are connecting two hosts, helient and hserver with a peer to peer tunnel. The connection is is very simple: 10.0.1.2 (client) and we create a device tun5 (this could also be an other number). The procedure

- Connect with SSH using the tunnel option -w
- Configure the IP addresses of the tunnel. Once on the server and once on the client.

## Connect to the server

Connection started on the client and commands are executed on the server

### Server is on Linux

Server is on FreeBSD cli># ssh -w5:5 root@hserver cli># ssh -w5:5 root@hserver srv># ifconfig tun5 10.0.1.1 netmask 255.255.255.252 srv># ifconfig tun5 10.0.1.1 10.0.1.2 # Executed on the server shell # Executed on the server shell

## Configure the client

Commands executed on the client:

## 11.5 Sign the certificate

The certificate request has to be signed by the CA to be valid, this step is usually done by the vendor. Note: replace "servername" with the name of your server in the next commands.

```
# mv newkey.pem servernamekey.pem
                                                 # openssl ca -policy policy_anything -out servernamecert.pem
-config /etc/ssl/openssl.cnf -infiles new.pem
                                                                                                                                          # cat newreq.pem newkey.pem > new.pem
```

Now servernamekey.pem is the private key and servernamecert.pem is the server certificate

# 11.6 Create united certificate

with it well. Create a file servername pem containing both the certificate and key. general, this is also easier to handle, but the file has to be kept securely!. Apache also can deal with it well. Create a file servername nem containing both the con

- Open the private key (servernamekey.pem) with a text editor and copy the private key into the "servername.pem" file.
- Do the same with the server certificate (servernamecert.pem)

The final servername.pem file should look like this:

```
 \label{eq:micxqibaakbgQDutwy+o/xZ/[...]} $$ qK5LqQgT3c9dU6fcR+wuSs6aejdEDDqBRQ----END RSA FRIVATE KEY----
                                   MIIERzCCA7CgAwIBAgIBBDANB[...]iG9w0BAQQFADCBxTELMAkGA1UEBhMCREUx
                                                                                   --BEGIN CERTIFICATE--
-END CERTIFICATE --
                                                                                                                                                                                                       -BEGIN RSA PRIVATE KEY--
```

What we have now in the directory /usr/local/certs/

certs/servernamecert.pem (server signed certificate) certs/servernamekey.pem (server private key) CA/cacert.pem (CA server public key) certs/servername.pem (server certificate with private key) CA/private/cakey.pem (CA server private key,

Keep the private key secure!

# 11.7 View certificate information

To view the certificate information simply do

```
# openssl s_client -connect cb.vu:443
                       # openssl x509 -text -in servernamecert.pem
# openssl req -noout -text -in server.csr
     # View the certificate info
# View the request info
# Check a web server certificate
```

### CVS

Server setup (p35) | CVS test (p36) | SSH tunneling (p37) | CVS usage (p37)

## 12.1 Server setup

### Initiate the CVS

Decide where the main repository will rest and create a root cvs. For example /usr/local/cvs (as

```
# cvs commit config
                                                                                                                                                            # mkdir -p /usr/local/cvs
                                                               cd CVSROOT
                                                                                                                                           setenv CVSROOT /usr/local/cvs
                                                                            cvs checkout CVSROOT
                                                                                                   cd /root
                                                                                                                      cvs init
 >> writers
                                          is)
 Create a writers
                                                                                                                      Creates all internal CVS config
                                                                              Checkout the config files to modify then
                                                                                                                                         Set CVSROOT to the new location
 file
(optionally also readers)
                                                                                                                                           (Local)
```

## SSL CERTIFICATES

So called SSL/TLS certificates are cryptographic public key certificates and are composed of a public and a private key. The certificates are used to authenticate the endpoints and encrypt the data. They are used for example on a web server (https) or mail server (imaps).

## 11.1 Procedure

- We need a certificate authority to sign our certificate. This step is usually provided by a vendor like Thawte, Verisign, etc., however we can also create our own.
  - Create a certificate signing request. This request is like an unsigned certificate (the public part) and already contains all necessary information. The certificate request is normally sent to the authority vendor for signing. This step also creates the private key on the local machine.
- Sign the certificate with the certificate authority. If necessary join the certificate and the key in a single file to be used by the application (web server, mail server etc.).

## 11.2 Configure OpenSSL

to your settings so you know where the files will be created. Here are the relevant part of We use /usr/local/certs as directory for this example check or edit /etc/ssl/openssl.cnf accordingly openssl.cnf:

```
Where the issued certs are kept
                                                         Where the issued crl are kept
                   Where everything is kept
                                                                              database index file.
                   = /usr/local/certs/CA
                                                                              $dir/index.txt
                                          $dir/certs
                                                           $dir/crl
[ CA_default ]
                                                                              database
                                                           crl dir
                                          certs
```

Make sure the directories exist or create them

```
# Only if serial does not exist
                                                          mkdir certs crl newcerts private echo "01" > serial
mkdir -p /usr/local/certs/CA
                              cd /usr/local/certs/CA
```

you intend to get a signed certificate from a vendor, you only need a certificate signing request (CSR). This CSR will then be signed by the vendor for a limited time (e.g. 1 year).

# 11.3 Create a certificate authority

If you do not have a certificate authority from a vendor, you'll have to create your own. This step is not necessary if one intend to use a vendor to sign the request. To make a certificate authority

```
# openss1 req -new -x509 -days 730 -config /etc/ss1/openss1.cnf \
                                                      -keyout CA/private/cakey.pem -out CA/cacert.pem
```

# 11.4 Create a certificate signing request

certificate with its private key. If your application do not support encrypted private key (for example To make a new certificate (for mail server or web server for example), first create a request UW-IMAP does not), then disable encryption with -nodes.

```
# No encryption for the key
                                                                              openss1 req -nodes -new -keyout newkey.pem -out newreq.pem \
# openss1 req -new -keyout newkey.pem -out newreq.pem \
                                         -config /etc/ssl/openssl.cnf
                                                                                                                -config /etc/ssl/openssl.cnf
```

Keep this created CSR (newreq.pem) as it can be signed again at the next renewal, the signature onlt will limit the validity of the certificate. This process also created the private key newkey. pem.

34

## — VPN with SSH

```
# Client is on FreeBSD
cli># ifconfig tun5 10.0.1.2 netmask 255.255.255.252 # Client is on Linux
cli># ifconfig tun5 10.0.1.2 10.0.1.1
```

The two hosts are now connected and can transparently communicate with any layer 3/4 protocol using the tunnel IP addresses.

## 6.2 Connect two networks

24. The procedure is similar as above, we only need to add the routing. NAT must be activated on In addition to the p2p setup above, it is more useful to connect two private networks with an SSH VPN using two gates. Suppose for the example, netA is 192.168.51.0/24 and netB 192.168.16.0/ the private interface only if the gates are not the same as the default gateway of their network. 192.168.51.0/24 (netA) gateA <-> gateB 192.168.16.0/24 (netB)

- Connect with SSH using the tunnel option -w.
- Configure the IP addresses of the tunnel. Once on the server and once on the client.
- Add the routing for the two networks.
- If necessary, activate NAT on the private interface of the gate.

The setup is started from gateA in netA.

## Connect from gateA to gateB

Connection is started from gateA and commands are executed on gateB.

### gateB is on Linux

```
36
                                                  gateB># ifconfig tun5 10.0.1.1 netmask 255.255.255.255.8 Executed on the gateB shell gateB># route add -net 192.168.51.0 netmask 255.255.255.0 dev tun5 gateB># echo 1 > /proc/sys/net/ipv4/ip_forward # Only needed if not default gr gateB># iptables -t nat -A POSTROUTING -o ethO -j MASQUERADE
gateA># ssh -w5:5 root@gateB
```

## gateB is on FreeBSD

```
Mg
                            the gateB shell
                                                                                       Only needed if not default
Creates the tun5 devices
                                                                                                                      see NAT (page 17)
                               Executed on
                                                        gateB># route add 192.168.51.0/24 10.0.1.2
                               gateB># ifconfig tun5 10.0.1.1 10.0.1.2
                                                                                    gateB># sysctl net.inet.ip.forwarding=1
                                                                                                                         gateB># natd -s -m -u -dynamic -n fxp0
                                                                                                                                                     gateA># sysctl net.inet.ip.fw.enable=1
gateA># ssh -w5:5 root@gateB
```

### Configure gateA

Commands executed on gateA:

### gateA is on Linux

```
gateA># route add -net 192.168.16.0 netmask 255.255.255.0 dev tun5
                                                                                                                                                                    gateA># iptables -t nat -A POSTROUTING -o eth0 -j MASQUERADE
gateA># ifconfig tun5 10.0.1.2 netmask 255.255.255.252
                                                                                                                   gateA># echo 1 > /proc/sys/net/ipv4/ip_forward
```

## gateA is on FreeBSD

```
# see NAT (page 17)
                                      gateA># route add 192.168.16.0/24 10.0.1.2
gateA># ifconfig tun5 10.0.1.2 10.0.1.1
                                                                            sysctl net.inet.ip.forwarding=1
                                                                                                            gateA># natd -s -m -u -dynamic -n fxp0
                                                                                                                                         gateA># sysctl net.inet.ip.fw.enable=1
                                                                            gateA>#
```

Ine two private networks are now transparently connected via the SSH VPN. The IP forward and NAT settings are only necessary if the gates are not the default gateways. In this case the clients would not know where to forward the response, and nat must be activated.

<sup>21.</sup>http://support.apple.com/kb/ht1578

7 RSYNC

## Encrypt Partitions

good... Here some examples: restarted. A trailing slash (and the absence thereof) has different meanings, the man page is Rsync can almost completely replace cp and scp, furthermore interrupted transfers are efficiently

Copy the directories with full content:

```
# rsync -aR --delete-during /home/user/ /backup/ # use relative (see below)
# /opt/local/bin/rsync -azv --iconv=UTF-8-MAC,UTF-8 ~/Music/flac/ me@server:/dst/
                                                                                                                                                                                                   # rsync -a /home/colin/ /backup/colin/
                                                                                                                                                       rsync -a /var/ /var_bak/
# convert filenames OSX UTF8 to Windows UTF8
                                                                                                                                                                                                   # "archive" mode. e.g keep the same
```

default and will use the ssh key if they are set. Use ":" as with SCP. A typical remote copy: Same as before but over the network and with compression. Rsync uses SSH for the transport per

```
\# rsync -a 'user@server:My\ Documents' My\ Documents \# Quote AND escape spaces for the remote shell
                                                                                  # rsync -axSRzv /home/user/ user@server:/backup/user/ # Copy to remote
```

remote directory will have the structure /backup/home/user/. This is typically used for backups. Exclude any directory tmp within /home/user/ and keep the relative folders hierarchy, that is the

# rsync -azR --exclude=tmp/ /home/user/ user@server:/backup/

Use port 20022 for the ssh connection:

# rsync -az -e 'ssh -p 20022' /home/colin/ user@server:/backup/colin/

of /backup is defined by the configuration in /etc/rsyncd.conf. The variable RSYNC\_PASSWORD can Using the rsync daemon (used with "::") is much faster, but not encrypted over ssh. The location be set to avoid the need to enter the password manually.

```
# rsync -axSRz ruser@hostname::rmodule/backup/ /home/
                                          rsync -axSRz /home/ ruser@hostname::rmodule/backup/
# To copy back
```

## Some important options:

```
--delete-after
                                                               --exclude=PATTERN
                            -delete-during
                                                                                           --one-file-system
                                                                                                                            --sparse
                                                                                                                                                          --hard-links
                                                                                                                                                                                                                                                        --archive
                                                                                                                       handle sparse files efficiently
                                                                                                                                                                                                                                                        archive mode; same as -rlptgoD (no -H)
receiver deletes after transfer, not before
                                                                                                                                                                                      use relative path names
                            receiver deletes during xfer, not before
                                                                                                                                                                                                                       recurse into directories
                                                                                                                                                          preserve hard links
                                                            exclude files matching PATTERN
                                                                                      don't cross file system boundaries
```

## 7.1 Rsync on Windows

system variables: # Control Panel -> System -> tab Advanced, button Environment Variables. convenient for automated backups. Install one of them (not both) and add the path to the Windows Files\cwRsync\bin or C:\cygwin\bin. This way the commands rsync and ssh are available in a Edit the "Path" system variable and add the full path to the installed rsync, e.g. C:\Program Windows command shell Rsync is available for Windows through cygwin or as stand-alone packaged in cwrsync<sup>15</sup>. This is very

## Public key authentication

Automatic backups have to avoid a user interaction, for this the SSH public key authentication can Rsync is automatically tunneled over SSH and thus uses the SSH authentication on the server be used and the rsync command will run without a password.

All the following commands are executed within a Windows console. In a console (Start -> Run -> cmd) create and upload the key as described in SSH, change "user" and "server" as appropriate. If the file authorized\_keys2 does not exist yet, simply copy id\_dsa.pub to authorized\_keys2 and

15.http://sourceforge.net/projects/sereds

'geom\_eli\_load="YES"' >> /boot/loader.conf # or as module:
# or do: kldload geom\_eli

## Use password and key

I use those settings for a typical disk encryption, it uses a passphrase AND a key to encrypt the master key. That is you need both the password and the generated key /root/adl.key to attach the partition. The master key is stored inside the partition and is not visible. See below for typical USB or file based image.

## Create encrypted partition

```
dd if=/dev/random of=/root/adl.key bs=64 count=1
geli init -s 4096 -K /root/adl.key /dev/adl
mount /dev/adl.eli /mnt
                            newfs /dev/adl.eli
                                                                dd if=/dev/random of=/dev/ad1.eli bs=1m
                                                                                                geli attach -k /root/adl.key /dev/adl
                                                                                         # this key encrypts the mater key
# -s 8192 is also OK for disks
# DO make a backup of /root/adl.key
                                Create file system
                                                                Optional and takes a long time
```

#### Attach

```
# mount /dev/ad1.eli /mnt
                    geli attach -k /root/adl.key /dev/adl
fsck -ny -t ffs /dev/adl.eli
                         # In
                      doubt check the file system
```

The detach procedure is done automatically on shutdown

```
# geli detach /dev/adl.eli
                          # umount /mnt
```

#### /etc/fstab

prompted when booting. The following settings are required for this example: The encrypted partition can be configured to be mounted with /etc/fstab. The password will be

```
/dev/adl.eli
                            geli_ad1_flags="-k /root/ad1.key"
                                           geli_devices="ad1"
           grep geli /etc/fstab
                                                         grep geli /etc/rc.conf
/home/private
 ufs
ΥW
 0
 0
```

## Use password only

the same as above, simply without the key file. Let's encrypt a file based image  $/\mathtt{cryptedfile}$  of 1 It is more convenient to encrypt a USB stick or file based image with a passphrase only and no key In this case it is not necessary to carry the additional key file around. The procedure is very much

```
geli
                                                                                                                                                                                         dd if=/dev/zero of=/cryptedfile bs=1M count=1000 # 1 GB file
geli detach md0.eli
                       umount /dev/md0.eli
                                                   mount /dev/md0.eli /mnt
                                                                             newfs -U -m 0 /dev/md0.eli
                                                                                                         geli attach /dev/md0
                                                                                                                                                          mdconfig -at vnode -f /cryptedfile
                                                                                                                                   init /dev/md0
                                                                                                                                   # encrypts with password only
```

It is now possible to mount this image on an other system with the password only

```
# mdconfig -at vnode -f /cryptedfile
mount /dev/md0.eli /mnt
                         geli attach /dev/md0
```

# 10.1 OS X Encrypted Disk Image

Don't know by command line only. See OS X Encrypted Disk Image<sup>20</sup> and Apple support<sup>21</sup>

19. http://www.freebsd.org/handbook/disks-encrypting.html 20. https://wiki.thayer.dartmouth.edu/display/computing/Creating+a+Mac+OS+X+Encrypted+Disk+Image

# 10 ENCRYPT PARTITIONS

Linux with LUKS (p32) | Linux dm-crypt only (p32) | FreeBSD GELI (p32) | FBSD pwd only (p33) | OS X image (p33) There are (many) other alternative methods to encrypt disks, I only show here the methods I know and use. Keep in mind that the security is only good as long the OS has not been tempered with. An intruder could easily record the password from the keyboard events. Furthermore the data is freely accessible when the partition is *attached* and will not prevent an intruder to have access to it this state.

### **10.1 Linux**

Those instructions use the Linux dm-crypt (device-mapper) facility available on the 2.6 kernel. In this example, lets encrypt the partition /dev/sdc1, it could be however any other partition or disk, or USB or a file based partition created with losetup. In this case we would use /dev/loop0. See file image partition. The device mapper uses labels to identify a partition. We use sdc1 in this example, but it could be any string.

## dm-crypt with LUKS

LUKS with dm-crypt has better encryption and makes it possible to have multiple passphrase for the same partition or to change the password easily. To test if LUKS is available, simply type # cryptsetup --help, if nothing about LUKS shows up, use the instructions below Without LUKS. First create a partition if necessary: fdisk /dev/sdc.

## Create encrypted partition

```
# dd if=/dev/urandom of=/dev/sdc1
# cryptsetup -y luksFormat /dev/sdc1
# cryptsetup -y luksFormat /dev/sdc1
# cryptsetup luksOpen /dev/sdc1 sdc1
# mks.ext3 /dev/mapper/sdc1
# unount -t ext3 /dev/mapper/sdc1 /mnt
# unount /mnt
# create ext3 file system
# unount /mnt
# create ext3 file system
# unount /mnt
# unount /mnt
# Detach the encrypted partition
```

#### 4*ttach*

```
# cryptsetup luksOpen /dev/sdc1
# mount -t ext3 /dev/mapper/sdc1 /mnt
```

cryptsetup luksClose sdc1

# umount /mnt

```
dm-crypt without LUKS
# cryptsetup -y create sdc1 /dev/sdc1 # or any other partition like /dev/loop0
# dmsetup ls
# mkfs.ext3 /dev/mapper/sdc1
# mount -t ext3 /dev/mapper/sdc1 /mut
# mount -/ mrt,
```

Do exactly the same (without the mkfs part!) to re-attach the partition. If the password is not correct, the mount command will fail. In this case simply remove the map sdc1 (cryptsetup remove sdc1) and create it again.

# Detach the encrypted partition

cryptsetup remove sdc1

### 10.2 FreeBSD

The two popular FreeBSD disk encryption modules are gbde and gell. I now use gell because it is faster and also uses the crypto device for hardware acceleration. See The FreeBSD handbook Chapter  $18.6^{19}$  for all the details. The gell module must be loaded or compiled into the kernel:

### — SUDO —

```
# ssh-keygen -t dsa -N '' # Creates a public and a private key # rsync user@server.ssh/authorized_keys2 . # Copy the file locally from the server # cat id_dsa.pub >> authorized_keys2  # Or use an editor to add the key # rsync authorized_keys2 user@server.ssh/ # Copy the file back to the server # del authorized_keys2
```

## Now test it with (in one line):

```
rsync -rv "/cygdrive/c/Documents and Settings/%USERNAME%/My Documents/" \ 'user@server:My\ Documents/'
```

### **Automatic backup**

Use a batch file to automate the backup and add the file in the scheduled tasks (Programs -> Accessories -> System Tools -> Scheduled Tasks). For example create the file backup.bat and replace user@server.

```
GECHO OFF

REM rsync the directory My Documents
SETIOCAL
SET CWRSYNC
SET CYGMIN=nontsec
SET CYGMIN=nontsec
SET CYGMIN=nontsec
SET WOLDPATH=%PATH*
REM uncomment the next line when using cygwin
SET PATH=%CMRSYNCHONE% BIN%PATH%
echo Press Control-C to abort
rsync -av "/cygdrive/c/Documents and Settings/%USERNAME%/My Documents/" \
'user@server:My\ Documents/"
```

### 8 SUDO

Sudo is a standard way to give users some administrative rights without giving out the root password. Sudo is very useful in a multi user environment with a mix of server and workstations. Simply call the command with sudo:

```
# sudo /etc/init.d/dhcpd restart # Run the rc script as root
# sudo -u sysadmin whoami # Run cmd as an other user
```

## 8.1 Configuration

Sudo is configured in /etc/sudoers and must only be edited with visudo. The basic syntax is (the lists are comma separated):

```
user hosts = (runas) commands # In /etc/sudoers
users one or more users or %group (like %wheel) to gain the rights
hosts list of hosts (or ALL)
runas list of users (or ALL) that the command rule can be run as. It is enclosed in ()!
```

commands list of commands (or ALL) that will be run as root or as (runas)
Additionally those keywords can be defined as alias, they are called User\_Alias, Host\_Alias,
Runas\_Alias and Cmnd\_Alias. This is useful for larger setups. Here a sudoers example:

```
# cat /etc/sudoers
# host aliases are subnets or hostnames.
Host_Alias DMZ = 212.118.81.40/28
Host_Alias DESKTOP = work1, work2
# User aliases are a list of users which can have the same rights
User_Alias ADMINS = colin, luca, admin
User_Alias DEVEL = joe, jack, julia
Runas_Alias DBA = oracle,pgsql
# Command aliases define the full path of a list of commands
```

32

29

Cmnd Alias SYSTEM = /sbin/reboot,/usr/bin/kill,/sbin/halt,/sbin/shutdown,/etc/init.d/

### Encrypt Files —

```
ALL
                                                                                                                                                                                                                                     DEVEL
                                                                                                                                                                                                                                                                                                                              Cmnd_Alias
                                                                                                                                                                                                                                                                                                                                                            Cmnd Alias
                        # anyone can mount/unmount a cd-rom on the desktop machines
                                                                                                     sysadmin
                                                                                                                              sysadmin
                                                                                                                                                      # User sysadmin can mess around in the DMZ servers with some commands
                                                                                                                                                                                                                                                              root, ADMINS

                                                                                                  # Can do anything outside the DMZ.
                                                                                                                                                                                                        Developers can debug the DMZ servers
                                                                                                                                                                                                                                ADMINS can do anything w/o a password. Developers have full right on desktops
```

**ENCRYPT FILES** 

### 9.1 OpenSSL

### A single file

Encrypt and decrypt:

```
# openssl aes-128-cbc -d -salt -in file.aes -out file
                                                         openssl aes-128-cbc -salt -in file -out file.aes
```

Note that the file can of course be a tar archive

## tar and encrypt a whole directory

```
openssl aes-128-cbc -d -salt -in directory.tar.aes | tar -x -f -
                                       tar -cf - directory | openss1 aes-128-cbc -salt -out directory.tar.aes
# Encrypt
# Decrypt
```

# tar zip and encrypt a whole directory

```
# openss1 aes-128-cbc -d -salt -in directory.tar.gz.aes | tar -xz -f -
                                                   tar -zcf - directory | openss1 aes-128-cbc -salt -out directory.tar.gz.aes # Encrypt
# Decrypt
```

- Use -k mysecretpassword after aes-128-cbc to avoid the interactive password However note that this is highly insecure. request.
- Use aes-256-cbc instead of aes-128-cbc to get even stronger encryption. This uses also more CPU.

#### 9.2 GPG

GnuPG is well known to encrypt and sign emails or any data. Furthermore gpg and also provides an advanced key management system. This section only covers files encryption, not email usage, signing or the Web-Of-Trust.

password and anyone who knows the password can decrypt it, thus the keys are not needed. Gpg adds an extention ".gpg" to the encrypted file names. The simplest encryption is with a symmetric cipher. In this case the file is encrypted with a

```
gpg -c file
gpg file.gpg
  # Decrypt file (optionally -o otherfile)
                   Encrypt file with password
```

### Using keys

For more details see GPG Quick Start<sup>16</sup> and GPG/PGP Basics<sup>17</sup> and the gnupg documentation<sup>18</sup> among others.

remember: The private and public keys are the heart of asymmetric cryptography. What is important to

#### 30

## Encrypt Files —

- Your public key is used by others to encrypt files that only you as the receiver can decrypt
  (not even the one who encrypted the file can decrypt it). The public key is thus meant to be
- Your private key is encrypted with your passphrase and is used to decrypt files which were encrypted with your public key. The private key must be kept secure. Also if the key or passphrase is lost, so are all the files encrypted with your public key.
- The key files are called keyrings as they can contain more than one key.

with the same name and email. Also you should use a "passphrase", not a simple password. name and email and optionally a comment. The comment is useful to create more than one First generate a key pair. The defaults are fine, however you will have to enter at least your full

```
# This can take a long time
```

C:/Documents and Settings/%USERNAME%/Application Data/gnupg/. The keys are stored in  $\sim$ /.gnupg/ on Unix, on Windows they are typically stored in

```
~/.gnupg/secring.gpg
                                 ~/.gnupg/pubring.gpg
# Can contain more than one private key
                                 Contains your public keys and all others imported
```

Short reminder on most used options:

- -e encrypt data
- -d decrypt data
- -r NAME encrypt for recipient NAME (or 'Full Name' or 'email@domain')
- -a create ascii armored output of a key
- -o use as output file

The examples use 'Your Name' and 'Alice' as the keys are referred to by the email or full name or partial name. For example I can use 'Colin' or 'c@cb.vu' for my key [Colin Barschel (cb.vu) <c@cb.vu>].

## Encrypt for personal use only

No need to export/import any key for this. You have both already.

```
# gpg -e -r 'Your Name' file
# gpg -o file -d file.gpg
# Decrypt. Use -o or it goes to stdout
                            Encrypt with your public key
```

## Encrypt - Decrypt with keys

First you need to export your public key for someone else to use it. And you need to import the public say from Alice to encrypt a file for her. You can either handle the keys in simple ascii files or use a public key server.

is only Alice will be able to decrypt it. For example Alice export her public key and you import it, you can then encrypt a file for her. That

```
# gpg
                                                                                                                              # gpg -a -o alicekey.asc --export 'Alice'
gpg --search-keys --keyserver subkeys.pgp.net 'Alice' # or get her key from a server
                                               --import alicekey.asc
                                                                                      --send-keys --keyserver subkeys.pgp.net KEYID # Alice put her key on a server
                                                                                                                                           # Alice exported her key in ascii file.
                                               # You import her key into your pubring.
```

# Once the keys are imported it is very easy to encrypt or decrypt a file:

# gpg -d file.gpg -o file	# gpg -e -r 'Alice' file
# Decrypt a file encrypted by Alice for you.	# Encrypt the file for Alice.

## Key administration

# gpgedit-key KEYID	# gpgfingerprint KEYID	# gpgdelete-secret-key NAME	# gpgdelete-keys NAME	# gpglist-secret-keys	# gpggen-revoke 'Your Name'	The KEYID follows the '/' e.g. for: pub	# gpglist-keys	
<pre># Edit key (e.g sign or add/del email)</pre>	# Show the fingerprint of the key	<pre># delete a secret key from local key ring</pre>	<pre># delete a public key from local key ring</pre>	# list private keys	<pre># generate revocation certificate</pre>	ior: pub 1024D/D12B77CE the KEYID is D12B77CE	<pre># list public keys and see the KEYIDS</pre>
